Our scan in Moscow silent but effective

Some of Britain's most brilliant research workers have left the country in recent years to work in laboratories in Moscow. And Berlin. And Warsaw. And hundreds of other cities from Bangkok to Washington.

They leave quietly by sea or air and always receive a rousing welcome when they reach their destination. These reliable workers are contributing to research on an international scale. But are they known to your organisation?

A new dossier (including colour wall chart) has been prepared on Stereoscan S4-10, in the opinion of many leaders of scanning electron microscopy, the world's most reliable research worker. S4-10s are now at work in nearly 700 laboratories in 24 countries. And more are leaving the country every month. Strike now. Beg, borrow or otherwise obtain the file on Stereoscan S4-10 and wait for that enigmatic package to arrive. It contains the SEM with these fully researched features:

- Individual meters for key parameters
- Fast changing of specimen and stages
- Easy chamber access with 6 ports
- Complete high capacity vacuum system
- Choice of electron emitters
- Optimised beam voltage
- Three independently controlled lenses
- Unique accessory range based on user needs
- Resolution guaranteed <100Å

the Searle products for research autumn bulletin

MOUSE ANTI THETA SERUM

It is generally accepted that all cells with the theta alloantigen are thymus-derived and the use of cytotoxic theta antisera to identify thymus-derived lymphocytes has been widely reported. The two specificities of theta antisera are available from Searle, anti theta-C3H and anti theta-AKR.

MICROCOCOCCUS DNA-DEPENDENT RNA POLYMERASE

This highly purified enzyme is invaluable for basic studies on RNA synthesis, and has recently been used for synthesising anti-mRNA strands, for analysing template properties of mammalian chromatin and for transcribing the 'sense' strand of ribosomal DNA cistrons with high fidelity.

RABBIT GLOBIN m RNA

Rapid developments in the purification of messenger RNA enable us to offer a highly purified preparation of 9S globin messenger from rabbit reticulocytes. This material will be suitable for studies on translation in a variety of cell free systems.

POLY (dT) CELLULOSE

Recently, it has been shown that most messenger RNA's contain long regions of polyadenylate. These regions will bind the messenger molecules to poly(dT) cellulose, thus effectively isolating them from ribosomal RNA.

Other Products

Purified Encephalomyocarditis virus—
in milligramme quantities.
Six HL-A tissue typing antisera
Cultured Human Lymphocyte cell lines—
in kilogramme quantities.
Ribonuclease Inhibitor

WE'RE WAY OUT! But we're sure we haven't gone too far

How would you like to go out to 200 wavenumbers every day?
Right now you probably don't go that far but we don't
blame you—it's not easy—not without our Model 577

Infrared connoisseurs who already know the Perkin-Elmer range of medium priced instruments value the high performance and unique Flowchart presentation plus the reliable day to day operation. Now with the Model 577 new features such as selectable time constants, more scan speeds and ordinate scale expansion add up to only one thing—better performance over a wider wavelength range. Convenience hasn't been forgotten either. Those who have suffered in the past should buy one just to enjoy the new gain setting control and the chart tear off bar. Send for your brochure and catalogue today.

Should Science Proceed Uncontrolled?

SCIENCE, as Peter Medawar put it, is the art of the soluble. Scientists do not venture forth into schemes of research without some indication that they will ultimately be successful in their work. This generally means two things: that their research must be completed in a reasonable amount of time by a reasonable number of people, and that it will not involve too many steps into the unknown at once. It is foolish to attempt to carry out jobs for which there is a serious lack of tools, experimental, mathematical or conceptual. Most research workers find it enough of a struggle to extend the capabilities of, say, electron microscopy without simultaneously looking for a digital computer that is a thousand times bigger than any existing at present and developing for themselves a mathematical framework within which to work. Research thus tends to be timely, not only in the sense of answering present needs, but in the sense of being appropriate to the competence of the times in which it is set.

This unromantic view of science—a view which nonetheless does not exclude or belittle the Newtons and Einsteins—raises an interesting question. Scientists in some sense regulate themselves by going for the soluble—the only way to remain sane and relatively satisfied. Science itself, however, has no comparable regulatory process to ensure that its growth is along the right lines.

Many would argue, of course that talking about right lines at all is a nonsense. Science, they would say, is what scientists care to make it by their research, and it is nobody's business to organise other people's labours in order to cause science to develop along the lines of some personally conceived grand scheme. Certainly one cannot but have sympathy with those subjected to Five Year Plans, Global Strategies, Milestones and other orderly ideas imposed on some branches of science that have been blessed with tidy-minded bureaucracy at the top. Such rigidity often seems to discount creativity in science and to equate a healthy science solely with one in which there are enough data to go round. Nevertheless the excesses of regulatory zeal manifested in certain places should not detract from the need to ask the question whether the development of science should be entirely freed of controls. Every year universities turn out hundreds of PhDs, possessing, in theory, the skills and qualifications to do scientific research. If their work comes within the sphere of influence of the customer/contractor relationship they will experience certain forces which bear some resemblance to market-place economics and they cannot afford to be too cavalier in their disregard of the customer even though he may not have a very clear idea of what he wants, only of what he can afford. If, on the other hand, they can stay in some university department into which the customer has not yet ventured they can be free of many external forces that might seek to dictate the content of their research. Anything that is soluble is permissible.

It may be objected that the peer review process prevents excesses from happening. Research work comes under

formal scrutiny by grant-giving bodies before it is started and again by the referees of learned journals when it is completed. It comes under more informal review in the continuous circulation of scientists around the community. Is this not adequate control? The difficulty with the peer review process is that it only affords the reviewer a very limited view of the science, as opposed to the scientist, and ultimately his answer must be yes or no. He may wish to say that the applicant be encouraged to work on a different problem. He may wish to have the perspective of seeing who else is applying, in order to ensure that money is most effectively spent. He may even, if sufficiently energetic, wonder about how the proposed work compares with proposals being made in other countries, since science supposedly transcends national frontiers. But how often is it possible to do anything about these broader issues? Likewise referees are frequently faced with manuscripts which are impeccable but which, if published, will be neither read nor used. The dilemma seems always to be that of being thought arrogant if one speaks one's mind and stands up for a particular view of the development of science. Yet, privately, scientists can regularly be heard to bemoan the way in which bandwagons are followed to the detriment of less spectacular, but very necessary, research, students are encouraged to move into already overcrowded fields and so on.

It is asking a lot of administrations for them to define guidelines for scientific as opposed to administrative direction. It is better that practising scientists—unfortunately the very ones who can least spare time from their research activities—should be deeply involved. Money for scientific research is not going to flow ever more freely in the future and scientists must ensure that their opinions are heard now about the way in which science should develop rather than risk having administrative and political solutions imposed on them from above.

100 Years Ago

MR. JAMES DALLAS, of Benakandy, Cachar, writing us on the subject of inherited peculiarities, says that a friend of his has a black-and-tan English terrier dog, two inches of the end of whose tail is folded back so acutely as to come in contact with the upper portion. A pup, of which the dog is the undoubted father, has inherited the paternal peculiarity, with the difference that, instead of the end of the tail being turned up, it is turned down.

NOBEL PRIZES

Physics Award for Tunnelling Research

Dr. Brian Josephson, a particularly young winner of the Nobel Prize.

THIS year's award of the Nobel Prize for Physics to Leo Esaki, Ivor Giaever and Brian Josephson recognises the importance of tunnelling phenomena in semiconductors and superconductors. According to the quantum theory, electrons have a small probability of tunnelling through a potential barrier which is impenetrable according to classical theory. The phenomena depend on this probability.

Semi-conductors or super-conductors

The tunnel diode, discovered by Esaki (University of Tokyo) in 1957, is a p-n junction in a semiconductor so heavily doped that both sides are degenerate. The space-charge layer in the junction forms the potential barrier. When a small voltage is applied to bias the junction in the forward direction electrons tunnel from the n side to the valence band on the p side. When the bias voltage is sufficiently great, however, the electrons on the n side will have energies within the energy gap on the p side; since there will be no allowed states to receive the electrons, the current will drop and the diode will have a negative resistance. When the forward bias is sufficiently large the electrons will be able to tunnel across to the conduction band on the p side, and the resistance will become positive again. These properties of the diode enable it to be used in high speed amplifiers and oscillators. Since the electron current is affected by other excitations in the semiconductor, the diode can be also used to study these

excitations.

Giaever, originally Norwegian and a mechanical engineer, switched to physics on joining the General Electric Research Laboratory, New York. Impressed by the analogy with semiconductors, he used tunnelling to study the superconducting energy gap. In this case, the potential barrier was an insulating layer (usually an oxide) sandwiched between two metals. If one metal is normal and one superconducting (the NIS sandwich) and if the temperature is low, electrons will be able to tunnel from normal metal to superconductor only if the voltage bias is sufficient to carry them over the gap. In 1960 Giaever announced the first observation of the energy gap by this method. Giaever also realised that there is an analogy between the superconductor/insulator/superconductor sandwich and the tunnel diode and that the former should, under suitable conditions, also have a negative resistance characteristic. This he observed and the effect is now being developed in devices. A fuller account of Giaever's discovery has been given by Schmitt in *Physics Today* (14, 38; 1961).

Subsequent theoretical work showed that the characteristic of the NIS sandwich provides a direct measure of the density of electronic states of a superconductor. Because of the effect of other excitations, notably the phonons, on the density of states the tunnelling characteristic can be used to study these other properties. This has helped to confirm the basic theory of superconductivity as well as to yield important information on the phonon spectra of superconductors.

Tunnelling Supercurrents

In 1962, in a two-page letter to *Physics Letters*, Josephson (University of Cambridge), then aged twenty-two, predicted that it would be possible for supercurrents to tunnel between superconductors and that this tunnelling would be accompanied by a number of interesting effects. Essentially, Josephson showed that the whole superconducting sandwich was a single superconductor governed by a single wave

function, and that there were low-lying many-electron states that carried small currents without dissipation. If a large current passed through the sandwich, a voltage V would appear across it and there would be a non-dissipative contribution to the electric current oscillating at the frequency $2eV/h$ independent of the material. If such a junction is placed in a microwave field, this supercurrent leads to steps in the current-voltage characteristic. Josephson also stated (and showed in detail in later papers) that a magnetic field would modulate the phase of the wave function across the junction in a way analogous to that in which the phase of a light wave depends on path length. The result is that the dependence of the maximum Josephson supercurrent through a junction on magnetic field produces a 'Fresnel diffraction pattern'. The story of Josephson's discovery has been told by Anderson in *Physics Today* (23, 23; 1970).

At the time John Bardeen was sceptical that the effect would be as large as Josephson predicted. At an international conference in 1962 there occurred one of those historic moments in physics, the young Josephson defending his theory against the doubts of the 'elder statesman'. Within a few months, experiment had vindicated Josephson.

Since that time many beautiful experiments have been performed that demonstrate the effects of a magnetic field on Josephson tunnelling and which show that the phase of a superconducting wave function is coherent over macroscopic distances (at least of the order of centimetres). The effect is the basis of sensitive devices for measuring magnetic fields, voltages and small currents, and junctions are under development as computer elements.

The a.c. Josephson effect has been detected and used to provide the most accurate value of the fundamental constant e/h ; this, in turn, has led to a reassessment of the values of the other fundamental constants. It is also used to provide a new voltage standard and is being developed for the generation, detection and mixing of electromagnetic waves.

Professor G. Rickayzen of the University of Kent at Canterbury describes the research work for which the Nobel Prize for Physics was awarded.

Recognition for Organometallic Chemistry

Professor P. L. Pauson of the University of Strathclyde summarises the work on organo-transition metal chemistry which has earned its two chief founders the 1973 Nobel Prize for Chemistry.

ERNST OTTO FISCHER and Geoffrey Wilkinson share this year's Nobel Prize for Chemistry for spearheading the spectacular advances in organo-transition metal chemistry during the past twenty years. Not only were they among the first to recognise in 1952 the unique structure of ferrocene but their success in synthesising other "metallocenes" and many related cyclopentadienyl-metal complexes opened up the whole field.

Sandwich Compounds

Wilkinson used the name "sandwich compounds" for the metallocenes to describe molecular architecture, a structure consisting of two parallel five-membered carbon rings (cyclopentadienyl groups) symmetrically arranged around the central metal atom. The rings may be regarded as having sextets of π electrons and the important consequence, the aromaticity of ferrocene, was recognised and demonstrated by R. B. Woodward. The extensive organic chemistry thus opened up continues to be widely explored, most intensively and successfully in A. N. Nesmeyanov's Moscow laboratory, whose recent work has revived interest in ferrocene derivatives as anti-anaemic agents. Despite some early commercial promise, for example, for vapour plating and as fuel additives—including anti-knock agents, where a cyclopentadienylmanganese compound has earned limited practical success—no major direct application has yet repaid the intense effort put into this field. Initially industrial interest was so strong that it was not uncommon for a new type of cyclopentadienyl complex to be synthesised independently in three industrial laboratories as well as in Fischer's and Wilkinson's laboratories. But the work of Fischer and Wilkinson gradually diverged as the field broadened.

Theoretical interest in these remarkable structures was no less intense than practical interest, and gradually deepening understanding helped greatly in extending the whole area of research. J. Chatt and L. A. Duncanson had taken an important step in 1953 by applying

M. J. S. Dewar's π -bonding ideas to explain the structure of the organometallic compound known longer than any other—Zeise's ethylene-platinum salt. The relationship to this and the cyclopentadienyl sandwiches of other known compounds, including some acetylene complexes first prepared by W. Reppe and his group as well as H. Reihlen's butadiene-iron complex, emerged gradually. During this period both Fischer and Wilkinson worked on a variety of related alkene, diene and triene complexes.

Professor Geoffrey Wilkinson

Suspicion that the most puzzling of the earlier discoveries, F. Hein's "polyphenylchromium" compounds, might also belong in the "sandwich" class received striking confirmation when E. O. Fischer and W. Hafner succeeded in synthesising the prototype: bisbenzene-chromium. With the impressive range of other arene-metal complexes subsequently synthesised in his laboratory, this will undoubtedly continue to be regarded as Fischer's most distinctive and important contribution.

More recently, most of his work has been concentrated on the intriguing carbene complexes, first prepared in his

laboratory as a result of a most skilful and purposeful search for suitable synthetic methods. These studies have taken him back much closer to the metal carbonyls, on which he worked as a student under W. Hieber, whom he succeeded in the chair of inorganic chemistry at the Technische Hochschule of Munich in 1964.

Fischer's entire scientific work to date has been done there and at the University of Munich (1957-64). He resisted calls to other chairs which would have taken him from his native city and further from the Alps which he loves and where he relaxes—usually in the company of his students, walking and skiing from an attractive chalet built with the proceeds of the bis-arene-chromium patents.

Return to Imperial College

Wilkinson—a Yorkshireman born in Todmorden—likewise holds office in his own alma mater, the Imperial College of Science and Technology, London. He returned there in 1956 after thirteen years in North America, having gone to Canada during the war to do radiochemical work in connection with the development of the atomic bomb and moving by way of California to the Massachusetts Institute of Technology and then Harvard.

Most of his "sandwich" work was carried out at Harvard where Al Cotton, co-author of his famous textbook, was the first student to work with him in this field. Among Wilkinson's contributions of that period, his use of the then quite new NMR techniques demonstrated their great potential in this field and led to later discoveries of many interesting aspects of the behaviour of organometallic molecules. Since returning to London, his interests have gradually moved to other areas, notably the transition metal alkyls (he has devised molecules of almost as surprising stability as the original "sandwiches") and catalysis (he found and studied some of the most active homogeneous hydrogenation catalysts).

It is in such catalytic aspects, and in the use as chemical intermediates of such metal complexes as Fischer's carbene derivatives, that greatest interest and promise of use resides at present; but regardless of future developments, this year's Nobel Laureates have added a remarkable chapter to chemical knowledge.

Short Notes

Mark V—A Sound Investment

DETAILS and engineering drawings for the Mark V "Jodrell Bank" radio telescope have now been sent out for tender. Tenders will be in early in January, 1974, said Professor Sir Bernard Lovell last week, and a decision on whether to go ahead with building the telescope will be made by the SRC next spring. Sir Bernard also said that the staff at Jodrell Bank are "very happy" with the final design, and he is confident that the high accuracy required for its construction can be achieved. Although the final decision on building the instrument cannot be made until tenders have been considered, there is an air of optimism at Jodrell Bank, engendered partly by the recent granting of formal planning permission to build the telescope in the Meifod valley.

Outside Manchester, there have been reports that this optimism might yet prove unfounded, since the SRC is at present considering two expensive astronomy projects, the Mark V and the Northern Hemisphere Optical Observatory (NHO). Opponents of the Mark V argue that if the SRC is forced to choose between these projects then the radio telescope is more likely to be axed, because of the rising cost of steel, many thousands of tons of which are needed in the construction of such an instrument. But that argument is a two-edged weapon; the Mark I telescope at Jodrell Bank is today worth more as scrap than it cost to build, and from that point of view, the Mark V is a more sound investment than the NHO. According to a spokesman for the SRC last week, however, both optical and radio astronomers can rest assured in the knowledge that "planning is proceeding on both these projects and there is no reason to suppose that a choice will have to be made".

BA Launches BASS

THE inaugural conference of the British Association Students' Section (BASS) next January is to be entitled 'The Social Responsibility of the Scientist within the Community' which is a fair summary of BASS's preoccupations, as it now sees them. Speakers will include not only Dr Magnus Pyke, secretary of the British Association, and Sir Peter Medawar but also Mr James Moorhouse, of Rio Tinto Zinc, who will put the industrialist's point of view.

The new section will be distinct from the British Association of Young Scientists (BAYS) and membership is not restricted to scientists or to members of universities. It will be chiefly concerned with the consequences of science rather than with acquainting the public with developments in science, which has

been one of the main objectives of the British Association itself.

The BASS plans to hold a yearly conference and to carry on year-round activities in local branches based on places of higher education. These will not attempt to compete with already established scientific societies in providing general lectures except in certain cases, such as the University of Exeter, where the scientific societies are felt to be inadequate; but they will be involved in projects decided at the previous conference. The projects may be on similar lines to those organised by the British Association proper—for example the study groups on the role of research in higher education, the ethics of biological research and so on. Certainly they will involve the collection and discovery of already available data rather than original scientific research, as there are no central funds available for branch activities. The BASS will provide for the first time a forum for student discussion of science-related topics at the national level; and its creation may mean a new lease of life for the British Association.

Drapes Off at the DoE

FOLLOWING the recommendations of the Select Committee on Science and Technology that government departments should give regular accounts of their research activities, the Department of the Environment has produced its first report on research and development (HMSO, £0.42). The report reveals that in 1973-74, a greater proportion of the department's research resources are to be devoted to planning and transportation, and to environmental pollution and resources, all at the expense of building and construction.

Research and Development in the Department of the Environment

	1972-73	1973-74*
	(£ million)	
Planning and transportation	4.9	10.3
Building and construction	7.2	8.4
Environmental pollution and resources	2.5	5.8
Other expenditure†	2.6	2.7
Total	17.2	27.2

* Planned programme.

† Includes grants-in-aid to research associations, the Centre for Environmental Studies and so on.

The expenditure involved is shown in the table, which reflects the transfer of funds from the Natural Environment Research Council according to the Rothschild recipe and from the Department of Trade and Industry. Much of the department's research effort is centred on its four research establishments—the Building Research Establishment, the Transport and Road Research Laboratory, the Hydraulics Re-

search Station and the Water Pollution Research Laboratory, which between them employ more than 1,400 scientists and engineers.

Soyuz-Apollo Project

THE second round of preparatory talks for the joint Soyuz-Apollo project (scheduled for 1975) was held in Moscow from October 1 to 18, 1973, and dealt with problems of flight ballistics, coordination of the Soviet and American control centres and problems of crew transfer between the craft. In connection with the latter topic, the Soviet team revealed full details of the cause of the Soyuz 11 disaster of June 30, 1971.

Although as early as July 4, 1971 a *Pravda* article by Academician Boris N. Petrov (a leading figure in the Soviet space programme) hinted at mechanical failure, and although it was later announced that the death of the three cosmonauts was caused by loss of cabin pressure on re-entry, the details remained a secret. Now, apparently on the insistence of the United States team, it has been revealed that the firing of twelve explosive bolts to disconnect the re-entry capsule from the orbiting craft was more violent than anticipated, and accidentally loosened a safety valve cap, thus triggering an exhaust valve, resulting in total loss of cabin pressure within 45 seconds.

Ground tests after the accident revealed that it would take 27 seconds to close the valve by hand—17 seconds longer than the crew could have remained conscious. Earlier Russian reports that two of the cosmonauts were found "with hand raised" would suggest that such an attempt was made. Like the fire in which three Apollo astronauts died, the Soyuz tragedy seems to have been caused by a 'safety' mechanism that could not be operated with sufficient speed. Also, like the American disaster, it has led to modifications of the craft, which were tested out by a space-suited two-man crew in the 2-day Soyuz 12 mission of September 1973.

What is a Quark?

In *Physics Reports* (8, 173; 1973) Lipkin quotes the following definition of a quark, from a standard German-English dictionary: Quark, m. curd, curds; slime, slush, filth; (fig.) trifle, rubbish, trash; (sl.) du verstehst einen—davon, you understand damn-all about it; den alten—aufrühren (fig.), stir up mud. -ig, adj. containing curds; dirty. -kase, m. soft or cream cheese.

This reminds one of the Prime Axiom of physics: everything is made up of smaller pieces. This, together with the Corollary (some of the pieces attract each other; some are repulsive), seems to sum up the subject adequately, although glossing over some details.

NEW WORLD

A Special Case for DDT Treatment?

by our Washington Correspondent

IN the past few years, bewhiskered caterpillars of the Douglas fir tussock moth have been quietly munching their way through nearly a million acres of fir forests in the north-western United States. The moth suddenly began a population boom in 1971, defied all predictions that the outbreak would end this year from natural causes, and is about to present the Environmental Protection Agency (EPA) with a serious dilemma. Should the ban on DDT, which was imposed last year after a long and bitter debate, be temporarily lifted so that the caterpillars can be sprayed when they hatch next spring? Last week, while American troops were on alert around the world and a domestic crisis was gripping the United States, a sub-committee of the House Agriculture Committee took time to hear about the caterpillars.

The moth is always present in the Pacific North-West, but it is usually relatively untroublesome, existing in small numbers in balance with its natural predators. Every so often, however, for reasons that have never been adequately explained, the moth undergoes an explosive population growth. Usually the epidemic suddenly ends in the third year, when the caterpillars all die off from a virus infection which spreads through the eggs during the winter months, and these periods of heavy infestation are then followed by several years of relative quiet. This time the moth refused to follow its traditional three-year cycle. According to the Forest Service, at the last count the insect had defoliated to some degree 657,000 acres in Oregon and Washington State and another 125,000 acres in Idaho. The committee was told last week that as many as 1.5 million acres of forests could be stripped next year if the infestation is not checked. The foresters in the area and the lumber companies that make their living from the trees want to kill the insects when they hatch next spring with the only pesticide they know will do the job—DDT. This does not appeal to environmentalist organisations which fought long and hard to get DDT banned, or the EPA which is understandably reluctant to allow use of a pesticide which it banned only a year ago amid a blast of publicity and a barrage of complaints from farmers, pesticide manufacturers and some scientists. The choice is, however, not

simply a matter of DDT or no DDT, and it is greatly complicated by the moth's failure during the past year to conform to its previous population trends.

To appreciate the basis of the EPA's dilemma, a little knowledge of the life cycle of the moth is required. Tiny tussock moth caterpillars hatch over a period of about a month in late May and early June from eggs laid during late August and September. The caterpillars go through five to seven moults, increasing in size as they eat first all the new foliage growth and then old foliage; they pupate in August and emerge in 10 to 18 days as adult moths. The female moth is wingless and mating takes place on the cocoon; she lays some 200 eggs in a mass and dies within a few weeks. The eggs remain on the trees during the winter and hatch in the spring. Thus, if the caterpillars are to be attacked with a pesticide, the application must come just as they first emerge, before they have had chance to start munching the foliage, and the pesticide should ideally remain active for a month or so to kill caterpillars that hatch late.

When a population explosion takes place, it usually goes undetected during

the first year, but becomes painfully obvious when caterpillars start stripping the trees in the second year. If left alone, the outbreak tends to end abruptly in the spring of the third year, because of the explosive spread of a nuclear polyhedrosis virus which kills off some of the caterpillars at the end of their first moult (instar). The infection spreads because the dying larvae infect foliage which is eaten by other caterpillars during their second instar, and so on—it is calculated that if 10% of the caterpillars are infected during their first instar, the entire population will be virtually wiped out by the end of June.

The problem is, however, that although the virus infection kills off the outbreak abruptly, it does not complete its work until a fair proportion of the caterpillars have survived long enough to munch foliage, and trees are still stripped even in the third year of an outbreak. The usual practice has thus been to spray infested trees with DDT in the spring of the third year of an outbreak but that was stopped in 1969, when the Department of Agriculture (the EPA was not then formed) banned the use of DDT on forest land.

The present outbreak began in 1971, and, by rights, should have ended

BOLL WEEVIL

An End in Sight

by our Washington Correspondent

WHILE a verbal battle was taking place in Washington last week over the use of DDT (see accompanying story), the US Department of Agriculture announced that it has successfully completed a programme which proves that it is technically possible to eradicate the boll weevil in the United States. One of the most destructive insect pests in the cotton fields, the boll weevil is now attacked with more insecticide than any other pest, and its elimination could save cotton farmers up to \$200 million a year in lost production.

The Department of Agriculture's announcement was based on the results of a two-year study of the use of integrated pest management techniques in a 5,000 square mile area in Mississippi, Alabama and Louisiana. The experiment involved the application of pesticides, the use of sex pheromones and, finally, the release of large numbers of sterile male insects. First, several limited pesticide applications were made in late

autumn to kill the last generation of weevils to reproduce that year, and to reduce the population which was due to hibernate during the winter. Then, in the spring, male sex pheromones were used to bait traps in and around the cotton fields (the boll weevil is one of the few species of insects where the male, and not the female, produces sex attractants). Finally, sterile males were released in the cotton fields in numbers far greater than those of the males that had survived the onslaught of pesticides the previous autumn.

Surveys conducted at the end of the second year of the experiment indicated that there was no evidence of boll weevils in 235 of the 236 cotton fields in the core of the experimental area. It should be pointed out, however, that it will be several years before the weevil can be eradicated by these techniques, because a national elimination plan must be formulated and approved by all the parties involved. Nevertheless, the experiment has raised hopes that one of the most destructive pests in the United States may at last be on the way out.

abruptly with a massive infection in June this year. Nevertheless, in March, the United States Forest Service and the States of Washington and Oregon petitioned the EPA to allow the use of DDT on the outbreak this spring. They wanted to use 200,000 pounds of the pesticide on about 500,000 acres of forests, to prevent third-year defoliation, and to make sure that the infestation did not spread any further.

The EPA sent a team of investigators to take a look at the area and they returned with the finding that the egg masses were contaminated with virus—albeit at a fairly low level—and their report said that there was every expectation that the population would collapse without the use of DDT. They did, however, allow the experimental use of four chemical alternatives to DDT—Zectran, Dylox, Sevin-4-oil, and Bioethanomethrin—and the testing of a polyhedrosis virus and the bacterium *Bacillus thuringiensis* against the caterpillars.

The virus infection has not worked. The moth spread to an area about twice that of the original infestation. There seems to be no explanation of why the virus failed to do its work, except for the possibility that it may not have been present in sufficiently high density to wipe out the population. As for the insecticides, all were moderately effective but not as good as DDT, and the microbial agents proved to be promising but they will not be available in sufficient quantities for use in a large outbreak.

An extensive survey is now being undertaken to examine the egg masses that have just been laid, to try to predict the course of the infestation next year. Some of the eggs will be hatched in laboratories next March, and that should give some indication of the chances of virus infection wiping the insects out next spring. If it seems that the population will collapse from virus infection, the EPA could again deny the use of DDT. But the repercussions of another wrong prediction are obvious. Alternatively, the agency could agree to the use of DDT to prevent final-year defoliation of the infested trees, but that would lay it open to charges from environmentalists that DDT was used in a situation that did not warrant it. Moreover, there is a fear that if the DDT ban is lifted in this case, the floodgates would be opened for special pleas in countless other cases.

The EPA has, in fact, already granted exemption from the DDT ban this year for the spraying of pea crops in Washington to kill pea leaf weevil. That decision was taken because no other pesticide was available, and it was used in a region where there is little water runoff or likelihood of damage to wildlife. Although the exemption from the

ban has not sparked off a rash of other formal requests to use DDT, a parade of witnesses before the House Agriculture Committee last week told of numerous cases in which they would love to break out the DDT spray.

The hearings themselves were concerned with a bill introduced by Congressman Mike McCormack, whose constituents in the state of Washington are up in arms about the EPA's handling of the matter. The bill would essentially force the administrator of the EPA to approve use of DDT whenever the Secretary of Agriculture requests it. In other words, it would strip the EPA of its control over DDT. Although the committee members who bothered to attend the hearings last week are in strong sympathy with the legislation—it would, after all, give the Agriculture Department, over which they are supposed to preside, more power—its chances of survival if it ever reaches the floor of the House are considered slim. It is unlikely that many congressmen would be willing to put such a sensitive matter back in the hands of a department so closely allied with the industry concerned.

If last week's hearings demonstrated one thing, it was that the emotion that surrounded the DDT debate has by no means diminished since the pesticide was banned. The committee room echoed to all the familiar arguments, emotive phrases and accusations of scientific malpractice that characterised the extensive public hearings on the matter last year. At least the committee staff showed what they thought of the proceedings. They spent most of the time reading magazines and newspapers while witnesses on both sides of the debate rehashed their arguments and congressmen asked a spate of naive questions.

TECHNOLOGY ASSESSMENT

Some Cash at Last

by our Washington Correspondent
THE Office of Technology Assessment (OTA) is in business at last, more than a year after Congress decided to set it up. The office, which will conduct analyses and offer advice to the legislative branch of the federal government on issues involving science and technology, has been given \$2 million to spend in the 8 months that now remain in the 1974 fiscal year. The money, which was contained in the Legislative Appropriations Bill, was delayed by a fight over an entirely unrelated matter (see *Nature*, 245, 284; 1973), but the holdup prevented the OTA from hiring staff, appointing a director or doing any work—in other words, the office existed in name only.

Although \$2 million is a good deal less than the \$5 million that the OTA's

backers were requesting for its first year of operation, the funds will allow a start to be made soon on a few specific problems, which will be tackled by *ad hoc* panels. The first move, however, will be for the OTA Board, which consists of six senators and six congressmen, and which is chaired by Senator Edward M. Kennedy, to appoint a full-time director for the office. Emilio Q. Daddario, a former congressman who was largely responsible for developing the legislation that led to the setting up of OTA, is expected to get the job early next month.

MARINER 10

Go for Take-off

by our Cosmology Correspondent

THE first spacecraft to use the gravity of one planet to help it on its way to another is due for launch on or about November 3. Mariner 10 will swing past Venus and on to Mercury, where the first encounter will take place around March 29, 1974. The spacecraft will, if all goes well, remain in a circum-solar orbit so that further encounters with Mercury will take place on September 22 and at roughly six-monthly intervals thereafter. The spacecraft should still be functioning for the second encounter, at least.

On the face of things the Venus observations form the more interesting part of the mission, since enough is now known about Venus to hint at a complex planet with slow retrograde spin, extensive cratering, and an active atmosphere. But so little is known about Mercury that any information from Mariner 10 will be invaluable. And at least Mercury is not obscured by cloud; two television cameras equipped with 150-cm Cassegrain telescopes will produce resolution of 1.5 km for the full coverage of the planet and 100 m for selected areas.

Apart from the television cameras Mariner 10 will carry six scientific experiments, including an infrared radiometer, an extreme ultraviolet experiment, a 'radio science' experiment, a magnetometer and two experiments to measure the solar wind (particularly inside the orbit of Venus) and the galactic cosmic radiation. The infrared experiments will, of course, provide estimates of the surface temperatures of both planets. On Mercury large temperature variations are to be expected, for a thin atmosphere (if there is one at all, a matter which should be settled by the ultraviolet measurements) will allow extreme heating of the side exposed to the Sun. And the relatively slow rate of rotation (once every 58.6 days) means that the night side can lose large quantities of heat by radiation.

NEWS AND VIEWS

Does Zodiacal Light Intensity Vary?

ZODIACAL light is the term used to describe the faint cones of light that extend away from the Sun in the ecliptic plane, or zodiac, of the sky. It is visible to the naked eye and can be best seen from a high mountain in the tropics where it appears in the western sky for an hour or so after the end of evening twilight, or in the east for a similar period before the beginning of dawn. The narrow cone of light stands up above the horizon and reaches about halfway to the zenith. It shares the apparent diurnal motion of the sky and during the night sinks below the western horizon until, two hours or so after its first appearance at the end of twilight, only the faint upper portions remain visible. The cone is widest at the base, where it is of comparable intensity to the Milky Way, and narrows and grows fainter towards its apex. Studies of the spectrum of this light indicate that it is caused by sunlight scattered from small, solid interplanetary dust particles. These dust particles pervade the entire Solar System and by scattering sunlight they produce about one-third of the total light shining on the Earth's surface on a moonless night (the remainder is due to airglow and background starlight). Again, using spectroscopic observations the Doppler shift of several of the Fraunhofer lines in the spectrum of the light can be measured. Radial velocities determined from these observations indicate that essentially all the dust particles are in direct orbits around the Sun.

It has been deduced from polarisation observations that the zodiacal light could be produced either by many very small particles (submicron) or by fewer larger particles having rough surfaces. The similarity between the spectra of zodiacal light and Sun light supports the latter hypothesis and it is now generally believed that most of the light comes from particles smaller than $10\ \mu\text{m}$ (masses less than $10^{-9}\ \text{g}$). Over a period of about 10,000 years these particles will be dragged into the Sun by the Poynting-Robertson effect, whereby the particles lose angular momentum due to the uniform re-radiation of adsorbed solar radiation. So if the dust cloud is in a steady-state condition there must be a continual source of small particles. The exact nature of this source is still in some doubt because the dust introduced must not only be of the right size but it must also be in the right place in the Solar System. A considerable fraction will come from the breakup of cometary nuclei as they pass close to the Sun and this process leads to the formation of streams of dust particles around the orbit of the comet. These dust streams then decay into the Solar System dust cloud. Asteroidal collisions could produce sufficient dust outside the Earth's orbit, which would slowly spiral into the Sun due to the Poynting-Robertson effect. Lunar ejecta produced by meteorite impact have also been suggested.

One way of deciding between these different possibilities is to investigate the temporal constancy of zodiacal light. Continual changes in the brightness as a function of, for example, the Earth's position around its orbit could indicate that the dust cloud was not equidense but was made up of a collection of individual toroidal particle

streams. Constant brightness could, on the other hand, indicate that asteroidal debris was the main component of the cloud and/or that the meteor streams only contain large particles (mass greater than $10^{-6}\ \text{g}$) which only over a period of about 10,000 years break up into smaller zodiacal dust particles and diffuse into the cloud. A third possibility is that new streams do contain many small particles but that these are perturbed from the stream orbit very quickly. It has also been suggested that the dust does not originate in either comets or asteroids but is just an extension of the outer solar corona and has a common physical origin. These last two suggestions would both give constant brightness.

Results of a satellite-borne experiment to measure the brightness of zodiacal light (6530 Å) as a function of ecliptic latitude and the position of the Earth around its orbit are set out on page 26 of this issue of *Nature*. The satellite used, D2A 'Tournesol', was in a low altitude orbit and reaching a maximum height of 700 km above the Earth's surface. Levasseur and Blamont of the Service d'Aéronomie du Centre National de la Recherche Scientifique obtain measurements of the zodiacal light intensity at 90° elongation, that is in the plane perpendicular to the Earth-Sun line, which agree very well on normal days (that is, for most solar longitudes) with previous measurements by other researchers. On certain days, however, the zodiacal light intensity increased by up to 100% above the normal value, and this increase lasted a few days. By making measurements in consecutive years Levasseur and Blamont found the variations in intensity to occur at the same positions around the Earth's orbit. They conclude that these increases were caused when the Earth passed through a meteor stream, the 100% increase on November 1971, which remained 50% above the normal level for six days around the maximum, being the result of an encounter with the Andromedid stream, a toroid of particles in space produced by the decay of comet Biela.

The April Lyrids have also been detected, and one very interesting fact emerging from the observations is that width of the stream of small dust particles detected by the zodiacal light observations appears to be twice as wide as the stream of much larger (mass $\sim 10^{-1}\ \text{g}$) particles observed as visual meteors. Levasseur and Blamont conclude that the cloud of zodiacal dust particles is not uniform but consists of a collection of streams of particles, created by the decay of recent comets; these streams have a relatively short lifetime and diffuse into a more general background on account of the Poynting-Robertson effect. Interparticle collisions and planetary perturbations can also cause this stream decay.

Interestingly, Alexander, Arthur, Bohn and Smith (*Space Res.*, **13**; 1973) have also detected increases of up to 100% in the density of picogram particles, in this case in selenocentric space, by using microphone sensors on board the satellites Lunar Explorer 35 and OGO III. These increases were found to coincide with the major meteor showers.

A slightly cautionary note, however, must be intro-

duced. Sparrow and Ney (*Science, N.Y.*, **181**, 438; 1973), who have been measuring the intensity of the zodiacal light for four years from the satellite OSO-5, have failed to detect any temporal variations in the brightness or polarisation and have concluded that this variation if present at all is less than $\pm 10\%$ of the mean value. Sparrow and Ney discount all the many previous observations which purport to show correlations between zodiacal light intensity and solar surface brightness, magnetic storms, lunar phases, the position of Comet Encke, the Earth's position around its orbit and the eleven-year solar activity cycle.

At present these contrasting observations make the choice of a hypothesis to explain the origin of the zodiacal dust cloud very difficult. D. W. H.

New Look at Chromatin

In the past, attempts to relate the structure of chromatin to its function have lacked incisiveness because it has not proved possible to test directly for the expression of a given gene. It can be argued, for example, that looking at the physical and chemical properties of chromatin or the rates of transcription *in vitro* from chromatin templates does not give conclusive results since they fail to establish a direct relationship between the observed phenomena and specific gene expression.

Because of this criticism some workers have tried to analyse the RNA transcribed *in vitro* from chromatin by hybridising it to homologous DNA in conditions of RNA excess. In this type of analysis increasing concentrations of RNA are hybridised to a fixed quantity of DNA until a saturation level is reached. From this figure the fraction of active DNA in chromatin was estimated and it was concluded that only certain of the DNA sequences in chromatin are transcribed. The same type of analysis has been used to compare the sequences of two RNA populations by comparative hybridisation. In some of these studies the RNAs transcribed from different chromatin templates were found to contain markedly different types of sequences (for example, Paul and Gilmour, *J. molec. Biol.*, **34**, 305; 1968). It was argued that the template activity of DNA in chromatin is restricted in such a way that only tissue specific sequences are transcribed and that this provides the basis for the observed differences.

As knowledge of the complexity of eukaryotic DNA developed it became apparent that such hybridisation studies only detect RNA sequences which are transcribed from the repetitive fraction of the DNA. Recent studies of Harrison *et al.* (*Nature*, **239**, 219; 1972) and Bishop *et al.* (*Nature*, **235**, 231; 1972; and *Nature new Biol.*, **241**, 204; 1973) have shown that a tissue specific mRNA, globin mRNA, is transcribed from the unique DNA fraction. If this is generally true for most other mRNAs, then RNA excess hybridisation studies will not reveal differences in messenger sequences. The fact that tissue specific differences were detected within the repetitive DNA fraction is therefore intriguing.

A new approach to the analysis of chromatin function is now available as a result of the recent demonstration that globin mRNA can serve as template for the RNA dependent DNA polymerase (reverse transcriptase) from avian myeloblastosis virus to give a complementary DNA

(cDNA) copy of globin mRNA. Several workers have devised kinetic analyses in which RNA populations can be tested for the presence of globin mRNA by hybridisation to cDNA. When applied to the RNA transcribed *in vitro* from chromatin this test provides a far more exact analysis.

At this year's Cold Spring Harbor Symposium two groups of workers reported studies in which RNA transcribed by *Escherichia coli* polymerase from haemopoietic chromatin was examined in this way. Gilmour and Paul of the Beatson Institute for Cancer Research, Glasgow, compared the RNAs transcribed from mouse foetal liver (a haemopoietic tissue) and mouse brain chromatin by hybridising the RNAs to cDNA complementary to mouse globin mRNA. The results show that RNA transcribed from foetal liver chromatin contains globin mRNA sequences (1–2 parts in 10^5), whereas RNA transcribed from brain chromatin contains no detectable sequences. Axel *et al.* at the National Institutes of Health, Bethesda (see *Proc. natn. Acad. Sci., U.S.A.*, **70**, 2029; 1973), made a similar comparison between RNAs transcribed from duck reticulocyte and duck liver chromatin and found that 7 parts in 10^5 of reticulocyte chromatin RNA corresponded to duck globin mRNA whereas liver RNA contained no globin sequences.

Both groups eliminated the possibility that the globin mRNA had arisen by contamination with cellular RNA rather than by *de novo* synthesis, by incubating the haemopoietic chromatin in the absence of polymerase and finding, after adding carrier RNA, no material hybridising to cDNA. Furthermore, Gilmour and Paul isolated the hybrid formed between cDNA and RNA transcribed from mouse foetal liver chromatin on CsCl gradients. By labelling the RNA with ^{32}P it was possible to estimate that most of the hybridisable RNA arose by polymerase action and not cellular contamination. These results demonstrate that the transcription of DNA in chromatin is restricted in a very specific way and that this property survives the chromatin isolation procedures. Moreover, the findings show that bacterial polymerase can transcribe the globin gene and that the sequences transcribed by it are subject to a control mechanism. The conclusions then are very similar to those obtained from the earlier experiments in which RNA excess hybridisation was used.

The finding that tissue specific differences exist in the RNA transcribed from reiterated DNA sequences may be of considerable importance. By annealing RNA transcribed from chromatin in conditions of DNA excess, Axel *et al.* demonstrated that most of the RNA is transcribed from unique DNA sequences and only a small part comes from repetitive DNA. A similar analysis of *in vivo* nuclear RNA by Melli *et al.* (*Nature*, **231**, 8; 1971) gives an analogous result. It is now becoming clear that there is a relationship between unique and repetitive sequences both in RNA and DNA. Firtel and Lodish (*J. molec. Biol.*, **79**, 295; 1973) examined the nuclear mRNA precursor of *Dictyostelium* and found that about 25% of the sequences are transcribed from repetitive DNA, the remainder being unique. Most of the repetitive sequence, which is at the 5' end of the RNA, is removed during nuclear processing; however, a small portion accompanies the RNA into the cytoplasm. Similarly, Dina *et al.* (*Nature new Biol.*, **242**, 101; 1973) found that mRNA from the polysomes of *Xenopus* embryos contain two types of sequence, one which hybridises to the repetitive DNA and the other which is complementary to unique

DNA. For *Xenopus*, Davidson *et al.* (*J. molec. Biol.*, **77**, 1; 1973) have presented evidence that the types of sequence are interspersed throughout the genome and they propose that 200–400 bases of unique sequence alternate with longer unique sequences of average length 600–900 nucleotides, large enough to accommodate a single gene.

It is attractive to speculate that the short repeated sequences represent control elements which regulate the transcription of adjacent unique sequences. As already noted some of these repeated sequences are transcribed and indeed tissue specificity in the repetitive sequences of *in vivo* RNA is demonstrable in the earlier experiments of Shearer and McCarthy (*Biochemistry*, **6**, 283; 1967). The possibility that there is a degree of specificity in the repetitive RNA sequences from different tissues provides an explanation of why RNA excess experiments with chromatin-primed RNAs show tissue specificity. Hence within the repetitive sequences there may be broad specificities which reflect in a general way the specific mRNA sequences of a given tissue. Obviously because of the relatedness of repetitive sequences and the present uncertainty about their function this is not a particularly definitive parameter of gene expression. Hybridisation to cDNA complementary for a known mRNA clearly offers the most exact method available.

At the Cold Spring Harbor Symposium, the Glasgow group also reported results which indicated how this new approach might be used to identify molecules concerned with the restriction of chromatin. It was found that when the structure of foetal liver chromatin is disrupted by dissociating the DNA and proteins in high salt-urea solutions and then the components reassociated by slowly dialysing away the salt, the resulting chromatin still serves as a template for globin mRNA sequences. This means that the specific way in which chromatin is assembled is an inherent property of the components themselves. Which are the molecules responsible for directing this self-assembly?

A preliminary investigation implicates molecules within the non-histone or acidic protein fraction of chromatin. Non-histone proteins from foetal liver were isolated free of DNA and histones on hydroxy-

apatite columns. This material was allowed to associate with mouse brain chromatin by the reconstitution process already described. It could be shown that globin mRNA sequences which are normally absent from brain chromatin transcripts are now detected in the RNA transcribed from brain chromatin reconstituted with liver non-histone proteins. This suggests that there is a component of liver non-histone which is responsible for controlling the expression of the globin gene.

The isolation and handling of non-histone proteins have now reached a stage where virtually pure fractions of individual components can be obtained. Although some of these are probably chromatin-associated enzymes or structural proteins rather than control elements, it is now possible for the first time to make this distinction and, hopefully by narrowing down the field, ultimately to identify the responsible molecules.

S. G.

MEDICAL RADIOLOGY

Benefits and Risks

from a Correspondent

PATIENTS undergoing medical radiology are subject to small, but not negligible, genetic and somatic hazards. If the risks and benefits could be quantified, a cost/benefit study could be undertaken and measures to reduce the detriment could be assessed realistically against the likely gain. This was the

main theme of a conference organised by the Society for Radiological Protection in Birmingham on October 9.

The evaluation of the risks involves four stages. First, the radiation doses to individual organs are determined by direct measurement or otherwise; next, for each organ the mean dose to the population is assessed, taking into account the number of patients involved, their age distribution and other factors; third, the biological effect of a given organ dose is estimated; finally, a monetary value is attached to a given detriment.

The radiation doses involved are known reasonably well. By far the largest contributor is diagnostic radiology and this field was reviewed by S. B. Osborn (King's College Hospital, London). The evidence is derived mainly from the 1960 and 1966 reports of the Adrian Committee. The mean genetically significant dose (GSD) from diagnostic X rays to the whole population of the United Kingdom is about 15 mrad yr⁻¹, and the annual mean bone marrow dose is about 32 mrad. In other countries the GSD ranges from 1 to 50 mrad depending on the amount of radiology undertaken and the techniques used. Osborn pointed out that very large variations occur from hospital to hospital and the United Kingdom detriment could be reduced considerably if all institutions reached the standard of the best: this could not, however, be achieved without additional expenditure.

The contribution of radiotherapy to the mean annual GSD is about 5 mrad, whereas that from radioisotope tests is currently about ten times lower. The use of unsealed radioisotopes, however,

Conditions for Restriction in *E. coli*

MANY strains of *Escherichia coli* recognise the DNA of other strains and of phage. Recognition is followed by hydrolysis of the invading DNA, with a strain-specific endonuclease, unless the DNA is modified (by glucosylation and methylation) or mutated—presumably at the recognition site (SB site). A DNA duplex with only one strand modified is protected from degradation. Some experiments by Hartman and Zinder, of the Rockefeller University of New York, suggested that in some FI phage crosses of DNA duplexes only one strand is mutated at an SB site. They wondered how this mutant hybrid would compare with a modified hybrid when challenged with restriction enzymes and so, together with their colleagues Vovis and Horiusha, designed experiments to tackle the problem. Next Wednesday's *Nature New Biology* (November 7) contains an account of this work.

DNA heteroduplexes were made

in vitro by annealing the wild-type DNA of phage FI with alkali denatured RFIII/PL (that is, full length, linear, double stranded DNA enzymatically prepared from the replicating form of the virus-RFI, with restriction enzyme PL). The resulting heteroduplex, RFII, is circular, double stranded with at least one single strand nick.

The phage FI has two sites SB₁ and SB₂ which confer susceptibility to *E. coli* B restriction. By making heteroduplexes in which one or other of the DNA strands was modified or mutated at the SB sites, and testing for restriction with *E. coli* enzyme B, it was possible to confirm that both modification and mutation of either strand of a DNA duplex at the SB site protect the molecule from restriction.

The authors were not able to determine whether SB mutant hybrids can be modified *in vivo* or *in vitro*, but they are at present working on this question.

is doubling every 3 yr. R. E. Ellis (University of Leeds) has found (ICRP Publication 17) that most individual radionuclide investigations give rise to somatic and genetic doses to patients comparable with those from X-ray examinations, but there are important exceptions and he proposed a set of maximum organ doses (for example, 5 rad for non-pregnant adults) for these tests.

The assessment of the biological effect of small radiation doses was discussed by J. Rotblat (St Bartholomew's Hospital Medical College, London). This is the most difficult step of all, since the effects must be extrapolated from the observed results of irradiation at relatively high dose levels. In the absence of direct evidence, a linear extrapolation is often assumed, but Rotblat thought that this may sometimes underestimate the effect. The evidence from Hiroshima indicates an annual death rate from radiation-induced cancer of all types of $\sim 6/10^6$ adults per rad. For young persons, however, the rate per rad seems to be several times higher, and it is still higher for embryos. For continuing exposure the induction rate depends on the latent period and the number of remaining years of life during which cancer may become manifest. Rotblat concluded that medical uses of radiation in the United Kingdom may lead to an annual cancer rate of 150–750, with perhaps a further 25–600 diseases or abnormalities of genetic origin.

G. Webb (National Radiological Protection Board) discussed the methodology and potential uses of a cost/benefit study in this field. Although a rigorous analysis is not yet feasible, useful results can still be obtained. The overall cost to society is reduced if patient doses are held at the lowest level consistent with a high rate of successful diagnosis and treatments. According to ICRP Report 22 the cost of the detriment associated with 1 man-rad is £10–£100. If the mean GSD to the UK population is 20 mrad, the annual cost of the genetic detriment alone is $\text{£}10^7\text{--}10^8$, a significant fraction of the total cost of the National Health Service ($\sim \text{£}2 \times 10^9$ yr⁻¹). Webb concluded that the British people can afford to invest a little more each year in the health of future generations.

PHARMACEUTICS

Safety of Contraceptives

from a Correspondent

A MEETING organised by the World Health Organisation was held in Geneva from September 16 to 20 to discuss the use of pharmacological models in the assessment of toxicity and side effects of

fertility regulating agents. The meeting reflected the uncertainty felt by many involved both in the development of new fertility regulating agents and the continued use of presently available ones concerning the assessment and monitoring of toxicity and side effects. A major part of the deliberations was concerned with the extent to which studies performed on animals could be extrapolated to man. The usefulness of the various tests of toxicity and anti-fertility carried out in a number of species was reviewed. To have predictive value these tests should be performed in species in which the reproductive mechanisms, toxic reactions and metabolic disposition of the agents are similar to those in humans. Because of the wide variability of these parameters in different species a number of different species would probably have to be used, an obviously unsatisfactory solution.

If animal models are unsuitable for assessing toxicity, the careful monitoring of subjects using the regulatory agents is of extreme importance and this again raises special problems. These agents are used by normal healthy women over long periods of time and often with little medical supervision. Side effects which occur with a high frequency would be quickly noted but those which occur with a low frequency would be much more difficult to detect. It is these low frequency side effects which are difficult, if not impossible, to detect in animals. As expected, the question of carcinogenicity of presently used hormonal contraceptives provoked much discussion, although those who suggest on theoretical grounds that the oral contraceptives might be carcinogenic in humans have difficulty in finding evidence to support their views. No satisfactory model is presently available to test for carcinogenicity. In considering contraceptive drugs the return of fertility at the end of the treatment period has to be ascertained. The possibility that women might become pregnant while taking, or shortly after having taken, the drug necessitates screening for teratogenic and mutagenic effects.

The requirements for toxicity testing of anti-fertility agents were discussed by representatives of the national drug regulatory agencies with particular consideration to the possibility of standardising many of the requirements on an international basis. These requirements must change in the light of new knowledge. The advantages and disadvantages of methods available for monitoring side effects in humans were also reviewed. The evaluation of reported side effects is complicated by the incidence of placebo reactions and these have not been taken into account in many trials. In addition, variations in response of women of different ethnic

origins to the same contraceptive drug are important. The special requirements for toxicity testing of long acting and of post-coital contraceptives, of spermicides, of various types of intrauterine devices and of the prostaglandins, all of which pose special problems, were also discussed.

It would not be advantageous to increase the amount of animal toxicity testing since this would increase the cost of research and development and, in the opinion of one speaker, "lead to a decreased interest on the part of the pharmaceutical industry to develop new agents. If this were to happen it may ultimately be more disastrous for the survival of large parts of the world population than the limited risk of even serious adverse effects of oral contraceptive preparations". It is hoped that advances in contraceptive technology would lead to a decrease in the amount of toxicity testing that needs to be carried out and hopefully shorten the time between animal testing and preliminary evaluation in humans.

Not unexpectedly, at the end one felt many questions remained unanswered, more research needed to be done, present methodology required improvement and many more discussions were imperative.

CELL BIOLOGY

Control of Proliferation

from a Correspondent

THE sixth meeting of the European Study Group for Cell Proliferation, which was held in Moscow from September 25 to 28 at the Institute of Molecular Biology of the Academy of Sciences of the USSR, took the general title "Molecular Mechanisms and the Control of Cell Proliferation".

Among the invited participants Professor J. M. Mitchison (University of Edinburgh) reviewed the concept of cell cycle markers, within which he included any detectable event which is associated with a localised region of the intermitotic period. Markers fall into three categories: morphological events such as mitosis or abrupt changes in the structure of the cell surface; biochemical events such as the initiation of DNA synthesis or the induction of specific enzymes; transition points at which metabolic inhibitors either begin or cease to be effective. The markers that are available within any one proliferating cell system indicate detectable points in the sequence of gene expression through the cell cycle. In some cases the blocking of one event in this sequence may suppress later events. Other examples can be found in which the sequence of events that make up the "DNA synthesis-division" cycle may to some extent be dissociated

from the sequence of the "cell growth" cycle.

At present a great deal of interest centres on the ability of proliferating cells to move into a state in which the DNA synthesis-division sequence is interrupted, as well as on their ability to respond to a suitable stimulus by continued proliferation. Yu. M. Vasiliev (Institute of Oncology, Moscow) reviewed the evidence for this in cultures of normal and neoplastic cells, which can enter a quiescent state either as a result of medium deprivation or confluency and renew proliferation following mechanical damage, the addition of fresh serum or treatment with a variety of chemical agents.

An important contribution to understanding of the nature of contact inhibition of growth came through the work of A. Zetterberg (Karolinska Institute, Stockholm) who has studied the approach to confluency in cultures of mouse kidney epithelial cells. When the cells were grown at low cell densities on a solid support, a thin web of cytoplasm formed around them, clearly demonstrable in the interference microscope, to which the term 'lamellar cytoplasm' was given. Detailed studies of the relationship between cell surface area and thymidine-labelling index led to the hypothesis that the cellular proliferation rate is largely determined by the area of the lamellar cytoplasm, with some dependence also on the nutrient quality of the medium. The biochemical changes that take place in confluent cell monolayers following stimulation by a change of medium were described by R. Baserga (Temple Medical School, Philadelphia). In cultures of normal human fibroblasts, an increase in the synthesis of non-histone chromosomal protein is detectable within 30 min of stimulation, closely followed by an increase in chromatin template activity, but neither of these early responses was found following stimulation of virus-transformed fibroblasts. The proffered papers, of which there were more than fifty, illustrated the existing wide interest in the control of cell proliferation both *in vivo* and *in vitro*, with sessions devoted to cell proliferation in haemopoietic tissues and to the possible role of chaperones in tissue homeostasis.

The European Study Group for Cell Proliferation, which was formed in 1967 under the auspices of the Coordinating Committee for Human Tumour Investigations, has now gained affiliation to the European Cell Biology Organisation. Its meetings have been designed to span a wide range of interests from the biochemistry of cell proliferation, through the study of cell and tissue kinetics, to the attempt to relate cell proliferation to therapeutic response in cancer. The next meeting will be in Amsterdam in the spring of 1975.

CELL BIOLOGY

Proteases and Growth

from a Correspondent

THE intriguing correlation between proteolytic activity, high agglutinability in the presence of plant lectins, and cell growth has been studied extensively in recent years. Transformed cells are readily agglutinable by lectins and continue to grow in conditions which arrest normal cells. Normal cells are much less readily agglutinated but on treatment with proteases they become agglutinable and, it is claimed, start growing again. It has been proposed, on the basis of these observations and others, that proteases produced by transformed cells act upon the surfaces of the cells and trigger them into growth.

This simple picture has now been questioned by Glynn, Thrash and Cunningham who report (*Proc. natn. Acad. Sci., U.S.A.*, **70**, 2676; 1973) that pronase treatment of 3T3 cells which have stopped growing renders the cells agglutinable by lectins but does not start them growing again. The increase in agglutinability, whatever it means, is in agreement with results from a number of laboratories, notably that of Burger (see *Fed. Proc.*, **32**, 91; 1973, for review) and Sachs, but the failure to stimulate

growth suggests that the alteration in cell surface produced by pronase and detected by lectins is not sufficient to trigger growth as has been suggested. Earlier reports have claimed that proteases, including pronase, when applied to cells, including 3T3, do start them growing (Burger, *Nature*, **227**, 170; 1970; Sefton and Rubin, *Nature*, **227**, 843; 1970).

There seems to be a direct conflict of results here. One might argue that Glynn *et al.* had damaged their cells so that they could no longer respond to growth stimuli. They show, however, that serum added after the pronase treatment is still effective in growth stimulation, although the response was not quite so marked as when the pronase treatment was omitted. They also state that the treated cells still respond to cortisol, another growth initiator.

The solution to this conflict could be in minor differences in procedure: perhaps the media of Burger and of Sefton and Rubin were less completely depleted of serum factors than those of Glynn *et al.* thus allowing or assisting the cells to respond to a growth stimulus by the pronase. The answer will have to await further experiments but it is clear from the results of Glynn *et al.* that one can separate the surface changes produced by proteases from any growth stimula-

Vesicular Stomatitis Virus Cores add Poly(A)

VESICULAR stomatitis virus (VSV) is a bullet shaped, negative strand virus that infects a wide variety of animal cells. Its genome is a single large piece of RNA that acts as a template for a virion-associated polymerase. This enzyme can be unmasked *in vitro* by non-ionic detergents such as NP 40. The RNA made by detergent-treated virions is considerably smaller than the genome, and complementary to it, but similar RNA species are found to be associated with the polysomes of VSV infected cells.

The MIT group of Baltimore, Lodish and colleagues have recently shown that these RNA molecules code for authentic VSV proteins in the wheat-germ cell-free protein synthesising system, so it seems legitimate to call them mRNA. Mudd and Summers (*Virology*, **42**, 958; 1970) showed three years ago that these messages contain poly(A), but a certain confusion has arisen as to when, where and how the poly(A) gets added.

Everybody agrees that the genome lacks the poly(U) tracts which would be necessary to code for the poly(A), but Roy *et al.* (*J. Virol.*, **11**, 915; 1973) recently said that the detergent-disrupted virions fail to make any poly(A). At the same time, Galet and Prevec (*Nature new Biol.*, **243**, 200; 1973) found that cytoplasmic extracts of VSV

infected cells would make mRNA which had the poly(A) stretches. These results seem to suggest that the host cell has a cytoplasmic enzyme which can add poly(A) to a viral RNA primer. This hypothesis is probably unnecessary, however, for Villareal and Holland report some experiments with detergent-treated VSV in *Nature New Biology* next Wednesday (November 7). They found that if they purified the cores by gel-filtration on Biogel A-5M they (1) obtained considerably higher activity and (2) the mRNA produced contained poly(A).

Unlike the activity found in Vaccinia virus cores (Kates and Beeson, *J. molec. Biol.*, **50**, 19; 1970), VSV cores need all four nucleoside triphosphates to make poly(A), suggesting that a primer is required to which the poly(A) is added. The nature of the primer is unclear, however, for Villareal and Holland find that even the small pieces of RNA produced by the defective interfering 'T particles' of VSV can have normal poly(A) added to them. Nor is it clear whether the primed but template-independent addition of poly(A) is made by the RNA-dependent RNA polymerase, or whether some other component of the purified cores—perhaps the so-called NS protein—is responsible.

tion. So, if proteolytic digestion assists in removing controls involved in density dependent inhibition of growth, which is not ruled out by these results, it does not manage it by itself. This conclusion is perhaps not surprising but worth stating in any case, especially for those cell biologists who are studying the role of serum factors and hormones in growth control.

THEORETICAL CHEMISTRY

Quantum Chemical Game

from our Molecular Physics Correspondent

ALL too often the complexities of the many-electron problem in chemistry lead to a frontal, and sometimes premature, assault by computer, relieved only occasionally by the elegance of a result from group theory or elsewhere. So familiar has this pattern become that it is a pleasant surprise to be presented with a simplification that is both unusual and elegant and, in its way, outright amusing.

Such a description may justly be applied to the paper entitled "A Game Theoretic Model for the Determination of Charge and Configuration in Metal Complex Compounds" by Haberditzl and Bartel (*Chem. Phys. Lett.*, **19**, 432; 1973). The authors show how at least one stage of the, in principle enormously complicated, problem of calculating the distribution of electrons between the central ion of a metal complex and its neighbours can be reduced to a simple exercise in the theory of games, the ion and its neighbours 'competing', as it were, for the electrons available. The type of idealised game involved proves to be quite a simple version of the 'two-person zero-sum' game in which two players seek an optimal course of action to maximise their chance of gain from a fixed premium. The various 'pure strategies' in the game correspond to suitable wave functions for the ion and the ligand system, and the 'payoff matrix' gives the hypothetical gain of electrons by the central ion for differing combinations, with due allowance for symmetry.

Of course the elements in the latter must be calculated by whatever means are to hand—inevitably some form of perturbation theory—and it is here that the full difficulty and scope for ingenuity in the problem very much remain. Yet, once the 'payoff' conditions have been specified, the optimal strategy for the central ion can be computed in a very simple manner and, moreover, in a single step (with considerable advantage over the laborious and somewhat fickle iterative methods used up to now).

Specialists will no doubt be quick to delimit the scope and practicality of the method, but it seems entirely possible that it will find applications to 'competi-

JUPITER

Plea for Observations

by our Cosmology Correspondent

PIONEER 10 is now rapidly approaching Jupiter, and in a recent issue of *Icarus* (**20**, 52; 1973) Coffeen, of the University of Arizona, puts in a plea for ground based observations to coincide with those of the probe. The period of particular interest is from November 28 to December 10, and there is a need for ground based photography, spectroscopy, photometry and polarimetry; during that period, Jupiter will be at a declination of $18^{\circ}.8$, with phase angle 9° , 4.1 h east of the Sun, so that southern latitude observations at around the time of evening twilight will be most effective.

tive' situations other than that between a metal ion and a ligand system. At the same time no one should go out of their way (as the authors conspicuously refrain from doing) to see anthropomorphic subtleties in the interatomic battle for electrons. The game-theory insight reveals a curious and perhaps far reaching new minimum principle, separates a messy calculation into two usefully distinct stages, and provides an illuminating mapping of one computational problem into a better known one. Quantum chemistry, perhaps of all theoretical sciences one of the most liable to be seen as a confusion of woods and trees, can certainly do with more adventurous touches of this kind.

PETROLOGY

Kimberlite Conference

from a Correspondent

ALTHOUGH kimberlites provide a more thorough sampling of the upper mantle than any other type of magmatic rock, they have never before formed the focal point of a major international conference. This was largely redressed when the first international conference on kimberlites was held, appropriately in South Africa, at the University of Cape Town from September 23–29.

In the session on kimberlite geology, descriptions were given of less well-known kimberlite provinces in North America, Greenland and South Africa, and M. Bardet (Bureau de Recherches Géologiques et Minières, Orléans) described kimberlites from West Africa that lack the normal kimberlite 'indicator' minerals (pyrope, picroilmenite) and suggested that many of these atypical kimberlites are yet to be discovered, having been missed by current prospect-

ing techniques. Although there was general agreement on an explosive origin of kimberlite diatremes, there was considerable debate as to whether the explosion mechanism results from high pressure gases within the kimberlite magma or is due to super-heating of groundwater by the ascending magma. In this context, the D/H and $^{18}\text{O}/^{16}\text{O}$ studies by S. M. F. Sheppard (Scottish Universities Research Reactor Centre, East Kilbride) indicated the involvement of warm groundwater in the formation of some diatreme kimberlites. Micro-probe analyses of the hitherto neglected groundmass minerals in the kimberlite matrix have now provided valuable information on the physical conditions prevailing during the crystallisation of the kimberlite matrix. This was exemplified by S. E. Haggerty (University of Massachusetts) whose work on the opaque phases has revealed considerable variation in the redox conditions, cooling rate and solid-solid, solid-gas and solid-liquid reactions during crystallisation. Haggerty also reported the occurrence in kimberlite of a new barium-vanadium titanate, and the first terrestrial occurrence of armalcolite.

In the sessions on xenoliths, two aspects made the most impact. Until now virtually no work has been carried out on the petrofabrics of kimberlite xenoliths, but A. Nicolas (University of Nantes) and B. Harte (University of Edinburgh) both reported a wide variety of deformation and recrystallisation features that have been imposed on these rocks within the upper mantle. The second aspect linked up strongly with the deformation studies of Nicolas. F. R. Boyd (Geophysical Laboratory, Washington) and P. H. Nixon (Department of Mines, Lesotho) showed that highly-sheared lherzolites have equilibrated at relatively high temperatures ($1,300\text{--}1,400^{\circ}\text{C}$) compared with the more normal granular lherzolites ($950\text{--}1,100^{\circ}\text{C}$), and together with the granular lherzolites could be used to infer a Cretaceous geothermal gradient; also Boyd and Nixon interpreted the shearing as due to the movement of the African Plate during the breakup of Gondwanaland.

The geochemistry of sheared lherzolites provided another focus of attention. They contain more CaO and Al_2O_3 than the granular lherzolites (and hence more potential basalt) but A. J. Erlank (University of Cape Town) showed them to be strongly depleted in both Nb and Zr. In addition N. Shimizu (Geophysical Laboratory, Washington) reported that the clinopyroxenes in the sheared lherzolites have very high K/Rb ratios ($2,000\text{--}2,200$), extremely high K/Cs ratios ($1,000,000\text{--}3,000,000$), and low $^{87}\text{Sr}/^{86}\text{Sr}$ ratios ($0.7027\text{--}0.7038$). This apparent clash between the major and trace element evidence, together with the wide-

spread occurrence of sheared lherzolites, underlines the need for more data on this important rock type.

The inclusions in diamonds have already provided valuable information on the phases coexisting with diamonds. With the increased sophistication of chemical techniques even more data have been provided by these unique sources of upper mantle information. For example, H. Allsopp (Bernard Price Institute, University of the Witwatersrand) reported U/Pb ages for diamonds from the Premier Mine, and H. Fesq (NPRU, University of the Witwatersrand) was able to show, on the basis of analysis of tiny drop-like inclusions within diamonds, that the liquid from which diamond crystallises is rich not only in siderophile elements but also in carbonate and sulphur.

The genesis of kimberlite was the subject of several papers on experimental petrology. There were two opposing viewpoints: (1) that kimberlite results from fractionation of a picritic parent, and (2) that kimberlite is an incipient melt from a phlogopite-bearing parental lherzolite. In the context of the second viewpoint, several authors reported that, although in the system peridotite-H₂O the initial melt is silica-saturated, when CO₂ is the dominant vapour phase the initial melt is silica-undersaturated. In a wider context, there seemed to be general agreement among delegates that there is a genetic link between kimberlite and carbonatite.

SUPERCONDUCTIVITY

Stimulated Tunnelling

from our Condensed Matter Correspondent Granqvist and Claeson of the Chalmers University of Technology in Gothenburg report in a recent issue of *Physical Review Letters* (31, 456; 1973) that they have observed some interesting new structure in the current-voltage characteristics of superconducting tunnel junctions which may, they suggest, be attributable to the stimulated emission of phonons.

Tunnelling is a phenomenon which occurs when two conductors are separated by a very thin non-conducting barrier: according to quantum mechanics there is a finite probability that an electron approaching the barrier from one side may spontaneously appear on the other side. If a small voltage is applied across the junction, a current will flow from conductor A which is at the higher potential, because it will have a large number of electrons which can tunnel across into empty states of the same energy in conductor B, on the other side of the barrier. A current does not flow in the reverse direction because there are no empty states in A of the same energy as that

of even the highest states in B. Nature permits only one electron per quantum state so that, if no empty states of appropriate energy are available, tunnelling cannot occur.

In the case of a superconductor, there is an energy gap 2Δ separating the superconducting, paired, electron states from the normal single electron states above them. For temperatures well below that of the superconducting transition, all the superconducting states will be occupied and all the normal ones empty. Tunnelling between two superconductors cannot occur, therefore, until the applied voltage V is sufficient to raise the potential of A to the extent that some of its occupied states reach the same energy as some of the empty states above the energy gap in B, which clearly requires $eV = 2\Delta$. The characteristic of such a junction is therefore: zero electron tunnelling current i up to the so-called gap voltage $2\Delta/e$; a very rapid increase in i as V just exceeds $2\Delta/e$, because of the particularly large density of permitted quantum states on either side of the energy gap; and a slower increase in i at larger values of V as tunnelling

takes place between states far from the energy gap whose density is much the same as that when the metal is in its normal state. The structure observed by Granqvist and Claeson consists of a series of unexpected wiggles in this latter part of the characteristic, and was only seen when electrode B was made exceedingly thin, about 1 nm.

The junctions were prepared by vacuum evaporation onto a germanium coated quartz substrate, using an elaborate technique in which the final, very thin, metal film electrode was deposited *in situ* in the cryostat at 0.3 K. The inner film was always of aluminium, which could be surface oxidised to produce the necessary layer of insulator, but a number of different superconductors were chosen for use as the thin outer electrode. The equipment was designed to measure, not i , but di/dV as a function of V , so the structure was resolved as sharp peaks. These peaks were invariably found to occur at potentials which were $2\Delta_i/e$ and $4\Delta_i/e$ above that of the main peak at $(\Delta_{Al} + \Delta_i)/e$, where $2\Delta_i$ is the energy gap appropriate to the very thin outer

Cavities in the Pulsar Magnetosphere

TAKE a highly magnetised sphere called a neutron star, and rotate it rapidly. Describe the region of space surrounding it. That, in essence, is the problem of the pulsar magnetosphere.

This is a very difficult problem, as it turns out, and indeed the complexity and variability of pulsar radiation lead one to expect that an apparently very simple problem may not have a simple, static, solution. Goldreich and Julian showed that the large electric fields induced by the rotating magnetic fields would be compensated for by a dense, charged magnetosphere, co-rotating with the star out to a 'velocity of light cylinder', where the co-rotation velocity approaches the velocity of light. Their solution was for a rotation axis coincident with a dipole magnetic axis. The perpendicular case is less tractable, but is known to have many similarities. The part of the problem which has so far received most attention is the configuration of the magnetic field lines as they cross the velocity of light cylinder. A new idea by Holloway (in *Nature Physical Science* next Monday, November 5) opens up the possibility of different configurations of charge inside the magnetosphere, and also gives a possible lead into the problem of the 'drifting sub-pulses'.

Holloway shows that a cavity within a positively charged portion of the magnetosphere would be stable, in the sense that the electric field at the boundary of the cavity would prevent

positive charges re-entering it. (There are no negative charges present, since there is complete charge separation in the magnetosphere.) The cavity could be a large sheet, dividing the magnetosphere into two regions. The situation is not necessarily static, however, since it is now possible for such a cavity to divide regions with different rotation speeds. In particular, there is likely to be a region which rotates faster than the star. This is interesting, because it provides a possible location for the emission of discrete sub-pulses of radio waves. These are often observed to 'drift', occurring earlier during each main pulse; the source thus super-rotates.

Differential rotation of this type would disturb the static picture, and the cavity would tend to fill through a viscous drift of particles. But there is a powerful dynamo in action around the star, and powerful centrifugal forces near the velocity of light cylinder. There is plenty of driving power available for re-creating the cavity. Holloway suggests that the centrifugal forces are responsible for depleting the charges in the cavity, but there is no detailed analysis as yet.

There is more to the problem of the rotating sphere than appears at first sight. It will not be sufficient to obtain a static self-consistent solution of the rotating charged magnetosphere. Holloway now explains that it may contain differential rotation; cavities, viscous drift and a centrifugal wind.

electrode and Δ_{Al} that for aluminium. This behaviour was consistently followed for outer electrode materials ranging from tantalum with $2\Delta_t = 1$ meV to lead with $2\Delta_t = 2.6$ meV, and in each case the structure diminished and finally disappeared as the outer electrode was made thicker.

Granqvist and Claesson suggest that these phenomena arise from the stimulated emission of phonons (quanta of lattice vibrational energy) in the outer electrode. The tunnelling electrons must arrive there with an energy $eV - \Delta_{Al} - \Delta_t$ above the top of its energy gap, and it is known that most of these first relax to states just above the gap through emission of so-called relaxation phonons of energy $eV - \Delta_{Al} - \Delta_t$, subsequently falling into paired superconducting states below the gap with emission of recombination phonons with energy $2\Delta_t$. If V is such that the recombination and relaxation phonons have the same energy, then there is a probability that the relaxation process will be stimulated by the $2\Delta_t$ phonons to occur faster than it otherwise would, so that, because a larger number of empty states will therefore be available into which tunnelling can occur, the current will seem to be anomalously large for that particular value of V , leading to a peak in di/dV . The required value of V is clearly $(\Delta_{Al} + 3\Delta_t)/e$, so one would expect a peak in di/dV , due to this effect, at $2\Delta_t/e$ above the gap voltage of $(\Delta_{Al} + \Delta_t)/e$, in agreement with experiment. Processes involving stimulated emission by two or more $2\Delta_t$ phonons should, by a similar argument, lead to further peaks at $4\Delta_t/e$, $6\Delta_t/e$ and so on, which is again consistent with experiment, although peaks beyond the one at $4\Delta_t/e$ are apparently too small to be observed.

The authors believe that these effects have not been observed previously because other workers were unable to prepare such thin outer electrodes: the thinner the electrode, the greater the density of recombination phonons, and so the larger becomes the probability of stimulated emission.

The density of these phonons must also be directly related to the recombination rate, so one would expect the magnitude of the new structure to depend markedly on the magnitude of the tunnelling current. A simple test of the theory would therefore be to repeat the experiment with junctions of different impedance, which can easily be arranged by varying the thickness of the oxide layer. The failure of a preliminary experiment of this nature to yield the anticipated result leads one to suspect that a complete explanation of Granqvist and Claesson's structure may turn out to be somewhat more complicated than they have suggested.

NUCLEAR PHYSICS

Resonance Transfer

from our Nuclear Structure Correspondent

WHEN an ion collides with an atom, the probability of electron transfer depends on the time they spend near each other (the collision time) and on the transfer time itself. If these times are similar, the transfer of one electron is most likely. If the collision time is twice the transfer time the electron can be transferred from the atom to the ion and back again, and so on. Since the collision time is inversely proportional to the relative velocity of the two atoms, the probability that an electron will be transferred from the atom to the ion attains peak values at a series of energies corresponding to one, three, five... transfers of the electron. A simple analysis shows that the cross section is of the form

$$\sigma(E) = A(E) + B(E)\cos^2(bE^{-1/2})$$

where $A(E)$ and $B(E)$ depend on the incident energy E and b is a constant. Measurements of electron transfer have been made by Ziembra and Eyerhart (*Phys. Rev. Lett.*, **2**, 299; 1959) that confirm this formula with surprising accuracy.

The simple theory works very well for the transfer of electrons between atoms because the electron is very light compared with the atoms themselves. If the transferred particle is comparable in mass to the colliding particles much of the simplicity is lost because of the increasing importance of recoil effects.

Resonant transfer processes, as they are called, have been looked for in nuclear reactions, and in particular it has been conjectured that they might be observable in neutron-proton collisions as multiple pion exchange or in heavy ion reactions as nucleon or cluster

exchange. Some indications of the characteristic signature of resonant transfer, a cross section following the formulae outlined here, have been found from time to time, but have not been substantiated by further work.

Recently a more convincing example of resonant transfer has been found in a study by Kelleter, Hrehuss and Mayer-Böricke (*Nucl. Phys.*, **A210**, 502; 1973) of the scattering of alpha particles by ${}^7\text{Li}$. The cross section of this reaction shows a rather irregular dependence on energy, as might be expected for such nuclei, but if it is plotted relative to the energy-averaged cross section an oscillatory behaviour is apparent, as shown in the figure. In particular, it shows an increase of 'wavelength' with energy very similar to that given by the resonant transfer, with small deviations readily attributable to the neglect of recoil and other effects in the simple theory. Since ${}^7\text{Li}$ can be considered as formed by a triton bound to an α particle, this oscillatory component of the reaction may be interpreted as due to transfer of a triton between the incident α -particle and the α particle in ${}^7\text{Li}$.

This interpretation is strengthened by an estimate of the parameter b , which is approximately given by $E_{\text{ex}}t_{\text{int}}/\hbar$, where E_{ex} is the average exchange energy and t_{int} the interaction time. The values of b obtained in this way are in qualitative agreement with those found by fitting the resonant transfer formula to the measured cross sections.

Further work needs to be done to develop a detailed theory of the process, taking into account the recoil effects and the presence of other reaction channels, and it would be useful if additional examples could be found experimentally. It is likely that such studies of resonant transfer reactions will provide a useful opportunity to develop nuclear reaction theory.

Ratio of the cross section for the elastic scattering of alpha particles by ${}^7\text{Li}$ to the energy-averaged cross section as a function of energy showing oscillatory structure interpreted as due to a resonant transfer of a triton between the two α particles. The dashed curves show the variation expected from the simple theory of the resonant transfer process.

The Logic of Animal Conflict

J. MAYNARD SMITH

School of Biological Sciences, University of Sussex, Falmer, Sussex BN1 9QG

G. R. PRICE

Galton Laboratory, University College London, 4 Stephenson Way, London NW1 2HE

Conflicts between animals of the same species usually are of "limited war" type, not causing serious injury. This is often explained as due to group or species selection for behaviour benefiting the species rather than individuals. Game theory and computer simulation analyses show, however, that a "limited war" strategy benefits individual animals as well as the species.

IN a typical combat between two male animals of the same species, the winner gains mates, dominance rights, desirable territory, or other advantages that will tend toward transmitting its genes to future generations at higher frequencies than the loser's genes. Consequently, one might expect that natural selection would develop maximally effective weapons and fighting styles for a "total war" strategy of battles between males to the death. But instead, intraspecific conflicts are usually of a "limited war" type, involving inefficient weapons or ritualized tactics that seldom cause serious injury to either contestant. For example, in many snake species the males fight each other by wrestling without using their fangs^{1,2}. In mule deer (*Odocoileus hemionus*) the bucks fight furiously but harmlessly by crashing or pushing antlers against antlers, while they refrain from attacking when an opponent turns away, exposing the unprotected side of its body³. And in the Arabian oryx (*Oryx leucoryx*) the extremely long, backward pointing horns are so inefficient for combat that in order for two males to fight they are forced to kneel down with their heads between their knees to direct their horns forward⁴. (For additional examples, see Collins⁵, Darwin⁶, Hingston⁶, Huxley *et al.*⁷, Lorenz⁸ and Wynne-Edwards⁹.)

How can one explain such oddities as snakes that wrestle with each other, deer that refuse to strike "foul blows", and antelope that kneel down to fight?

The accepted explanation for the conventional nature of contests is that if no conventional methods existed, many individuals would be injured, and this would militate against the survival of the species (see, for example, Huxley⁷). The difficulty with this type of explanation is that it appears to assume the operation of "group selection". Although one cannot rule out group selection as an agent producing adaptations, it is only likely to be effective in rather special circumstances¹⁰⁻¹². Consequently it seems to us that group selection cannot by itself account for the complex anatomical and behavioural adaptations for limited conflict found in so many species, but there must also be individual selection for these, which means that a "limited war" strategy must be differentially advantageous for individuals.

We consider simple formal models of conflict situations,

and ask what strategy will be favoured under individual selection. We first consider conflict in species possessing offensive weapons capable of inflicting serious injury on other members of the species. Then we consider conflict in species where serious injury is impossible, so that victory goes to the contestant who fights longest. For each model, we seek a strategy that will be stable under natural selection; that is, we seek an "evolutionarily stable strategy" or ESS. The concept of an ESS is fundamental to our argument; it has been derived in part from the theory of games, and in part from the work of MacArthur¹³ and of Hamilton¹⁴ on the evolution of the sex ratio. Roughly, an ESS is a strategy such that, if most of the members of a population adopt it, there is no "mutant" strategy that would give higher reproductive fitness.

A Computer Model

A main reason for using computer simulation was to test whether it is possible even in theory for individual selection to account for "limited war" behaviour.

We consider a species that possesses offensive weapons capable of inflicting serious injuries. We assume that there are two categories of conflict tactics: "conventional" tactics, *C*, which are unlikely to cause serious injury, and "dangerous" tactics, *D*, which are likely to injure the opponent seriously if they are employed for long. (Thus in the snake example, wrestling involves *C* tactics and use of fangs would be *D* tactics. In many species, *C* tactics are limited to threat displays at a distance, without any physical fighting. We consider a conflict between two individuals to consist of a series of alternate "moves". At each move, a contestant can employ *C* or *D* tactics, or retreat, *R*. If a contestant employs *D* tactics, there is a fixed probability that his opponent will be seriously injured: a contestant who is seriously injured always retreats. If a contestant retreats, the contest is at an end and his opponent is the winner. A possible conflict between contestants *A* and *B* can be represented in this way:

A's move C C C C C C C C C C C C C C C C C C C C C D

B's move C C C C C C C C C C C C C C C C C C C C C R

If a contestant plays *D* on the first move of a contest, or plays *D* in response to *C* by his opponent, this is called a "probe" or a "provocation". A probe made after the opening move is said to "escalate" a contest from *C* to *D* level. A contestant who plays *D* in reply to a probe is said to "retaliate". In the example shown above, *A* probes on his twelfth and twentieth moves; *B* retaliates after the first probe, but retreats after the second, leaving *A* the winner. At the end of a contest there are "pay-offs" to each contestant. The pay-offs are taken as measures of the contribution the contest has made to the reproductive success of the individual. They take account of three factors: the advantages of winning as compared with losing, the disadvantage of being seriously injured, and the disadvantage of wasting time and energy in the contest.

A "strategy" for a contestant is a set of rules which ascribe probabilities to the *C*, *D*, and *R* plays, as functions of what has previously happened in the course of the current contest. (No memory of what has happened in previous contests with the same or other opponents is assumed.) For computer simulation we programmed five possible strategies, each of which might be thought on *a priori* grounds to be optimal in certain circumstances. The strategies considered were as follows:

(1) "Mouse". Never plays *D*. If receives *D*, retreats at once before there is any possibility of receiving a serious injury. Otherwise plays *C* until the contest has lasted a preassigned number of moves.

(2) "Hawk". Always plays *D*. Continues the contest until he is seriously injured or his opponent retreats.

(3) "Bully". Plays *D* if making the first move. Plays *D* in response to *C*. Plays *C* in response to *D*. Retreats if opponent plays *D* a second time.

(4) "Retaliator". Plays *C* if making the first move. If opponent plays *C*, plays *C* (but plays *R* if contest has lasted a preassigned number of moves). If opponent plays *D*, with a high probability retaliates by playing *D*.

(5) "Prober-Retaliator". If making the first move, or after opponent has played *C*, with high probability plays *C* and with low probability plays *D* (but plays *R* if contest has lasted a preassigned number of moves). After giving a probe, reverts to *C* if opponent retaliates, but "takes advantage" by continuing to play *D* if opponent plays *C*. After receiving a probe, with high probability plays *D*.

The contestants were programmed as having identical fighting prowess, so that they differed only in the strategies they followed. The five strategies represent extremes, but from results with these it is possible to estimate the results likely to be found with intermediate types. The Hawk strategy is a "total war" strategy; Mouse, Retaliator, and Prober-Retaliator are "limited war" strategies. The question of main interest is whether individual selection will favour the former or one of the latter types.

The Simulation Test

The five strategies determine fifteen types of two-opponent contests. Two thousand contests of each type were simulated by computer, using pseudo-random numbers generated by an algorithm to vary the contests. The following probabilities were used: Probability of serious injury from a single *D* play=0.10. Probability that a Prober-Retaliator will probe on the opening move or after opponent has played *C*=0.05. Probability that Retaliator or Prober-Retaliator will retaliate against a probe (if not injured) by opponent=1.0. Pay-offs were calculated as follows: Pay-off for winning=+60. Pay-off for receiving serious injury=-100. Pay-off for each *D* received that does not cause serious injury (a "scratch")=-2. Pay-off for saving time and energy (awarded to each contestant not seriously injured) varied from 0 for a contest of maximum length, to +20 for a very short contest. The contest example shown earlier was one of the 2,000 Prober-Retaliator versus Prober-Retaliator contests.

Table 1 shows the average pay-off to each contestant in each type of contest. The number in a given row and

column is the pay-off gained by the row strategy when the opponent uses the column strategy. For example, in contests between Mouse and Hawk, the average pay-offs are 19.5 to Mouse and 80.0 to Hawk.

To tell whether a strategy is evolutionarily stable against the other four strategies, we examine the corresponding column in Table 1. For example, for Hawk to be an ESS, it is necessary that it be the most profitable strategy in a population almost entirely of Hawks. In such a population, a given animal of any type will almost always have a Hawk as opponent. Therefore the pay-offs in the "Hawk" column apply. These show that Mouse and Bully are both more successful than Hawk. Therefore natural selection will cause alleles for Mouse and Bully behaviour to increase in frequency, and alleles giving Hawk behaviour to decrease. Thus Hawk is not an ESS.

Examining the other columns, we see that Mouse is not an ESS because Hawk, Bully, and Prober-Retaliator average higher pay-offs in a population almost entirely of Mouse. Nor is Bully an ESS. However, Retaliator is an ESS since no other strategy does better, though Mouse does equally well. And the last column shows that Prober-Retaliator is almost an ESS.

How would we expect such a population to evolve? It will come to consist mainly of Retaliators or Prober-Retaliators, with the other strategies maintained at a low frequency by mutation. The balance between the two main types will depend on the frequency of Mouse, since the habit of probing is only an advantage against Mouse. For the particular values in Table 1, it can be shown that if the frequency of Mouse is greater than 7%, Prober-Retaliator will replace Retaliator as the predominant type. It is worth noting that a real population would contain young, senile, diseased and injured individuals adopting the strategy Mouse for non-genetic reasons.

Thus the simulation shows emphatically the superiority, under individual selection, of "limited war" strategies in comparison with the Hawk strategy.

Briefly, the reason that conflict limitation increases individual fitness is that retaliation behaviour decreases the fitness of Hawks, while the existence of possible future mating opportunities reduces the loss from retreating uninjured.

This general result will not be altered by moderate changes in the program parameters, though very large changes will alter it. One way would be by changing the probability of serious injury from a single *D* from 0.10 to 0.90. This would give advantage to "Pre-emptive Strike" policies, making Hawk an ESS. (Such species are probably rare, because excessively dangerous weapons or tactics would be opposed by kin selection.) Another way to make selection favour "total war" behaviour would be by giving the same pay-off penalty for retreating uninjured as for serious injury. This would correspond to a species where an individual fights only a single battle in its lifetime, on which its reproductive success entirely depends. Our choice of +60 for winning, 0 for retreating uninjured, and -100 for serious injury represents a species where males have more than one opportunity to gain a mate. Changing these values to +60, -100, and -100 respectively, would make Hawk the optimal strategy. Conversely, +60, 0,

Table 1 Average Pay-offs in Simulated Intraspecific Contests for Five Different Strategies

		Opponent				
		"Mouse"	"Hawk"	"Bully"	"Retaliator"	"Prober-Retaliator"
Contestant receiving the pay-off	"Mouse"	29.0	19.5	19.5	29.0	17.2
	"Hawk"	80.0	-19.5	74.6	-18.1	-18.9
	"Bully"	80.0	4.9	41.5	11.9	11.2
	"Retaliator"	29.0	-22.3	57.1	29.0	23.1
	"Prober-Retaliator"	56.7	-20.1	59.4	26.9	21.9

—500 would represent a long-lived species with numerous opportunities to gain mates, where individual selection would still more strongly favour cautious strategies.

Real Animals

Real animal conflicts are vastly more complex than our simulated conflicts. (An interesting study by Dingle¹⁵ shows that this holds true even at the lowly level of the mantis shrimp.) Probably our models are true to nature in emphasising a category distinction rather than an intensity distinction between "conventional" and "dangerous" tactics. In real animals, however, there exist not only the category distinction, but also individual differences in the intensity and skill with which each kind of tactic is employed. Also, in many species there are several categories of increasingly dangerous tactics, instead of only one.

The advantage from making a category distinction is that this simplifies behavioural requirements for limited conflict. It is probably easier for genetics to program a snake not to use fangs at all in certain situations than to program it to use fangs as intensively as possible up to intensity k , but not at intensities greater than k . Similarly, fair and foul blows are distinguished in boxing, and conventional and nuclear weapons in war.

Under the condition that any act of physical aggression is treated as a D act, the theoretical model will result in symbolic fighting by threat from a distance. This would be advantageous for a species that has an inherent difficulty in fighting physically at a safe level. For example, domestic and wild cattle, which have very dangerous horns and are somewhat clumsy in their charges, make much use of threat displays (stomping, pawing, bellowing). The model will not, however, give rise to conflict behaviour that is wholly symbolic and never backed up by physical aggression or other sanctions, since such behaviour would not be evolutionarily stable without some mechanism reducing the reproductive success of mutant individuals deficient in responding to the symbols. An interesting problem is how the felids, with their dangerous teeth and claws, limit their physical combats to non-fatal levels. Probably the explanation is that they have a hierarchy of many conflict categories and limit their probing to small escalations. Consequently, it takes repeated escalations to raise the conflict to the most dangerous level.

In most animal species there is probably a high correlation between prowess in C tactics and in D tactics. This means that C level conflict provides information to each animal about how its opponent is likely to perform if the conflict is escalated. This permits improvement in strategies over those used in the computer model. Instead of probing at random, an animal will be more likely to probe if its opponent is inferior in conventional fighting. On the other hand, if its opponent is very superior in conventional tactics, an animal will frequently retreat without waiting for its opponent to try a probe. Thus actual animals may combine Prober-Retaliator and Mouse capabilities.

If animals can adopt different strategies according to the opponent that confronts them, then an interesting possibility appears. The "Hawk" column of Table 1 shows that the best strategy against a Hawk is Mouse: that is, retreat immediately. If a species includes deviant individuals who follow the Hawk strategy and fight recklessly against every opponent, then it will be advantageous for ordinary members of the species to be able to estimate recklessness and avoid combat with Hawks. But if this happens, then it will be advantageous to simulate wild, uncontrollable rage. And in fact the threat displays of some species do have an appearance of maniacal fury, hence there probably is some advantage in acting this way. However, if most species members simulate insane rage when actually their fighting is limited and controlled, then selection will favour indi-

viduals who partly discount the threat displays, and "call the bluff" of the pseudo-Hawks.

This leads to the suggestion that it might be advantageous for an individual animal to be maniacal in an easily recognisable way that could not be counterfeited. A possible instance of this is the phenomenon of going "on musth", which occurs periodically in adult male elephants^{16,17}. The temporal glands secrete a dark brown fluid that runs down the face, giving a visual and olfactory sign that cannot be counterfeited. The madness of the animal "on musth" causes other elephants to avoid him, and this may give an increase in dominance status that persists for a time after the musth period is over.

Conflict in which Injury is Impossible

The previous section offers an explanation of why, in a species with offensive weapons capable of inflicting serious injury, escalated fighting may be rare or absent. In doing so, it raises a second problem. In a contest between opponents who are unable to inflict serious injury, victory goes to the one who is prepared to continue for a longer time. How are such contests decided?

Suppose that the pay-off to the victor is v . If a contest is ever to be settled, there must also be some disadvantage to the contestants in a long contest. If so, the only choice of strategy open to a contestant is of the period for which he is prepared to continue, and hence of the pay-off, say $-m$, he is prepared to accept. Thus if two contestants adopt strategies m_1 and m_2 , where $m_1 > m_2$, the pay-off to the first is $v - m_2$ and to the second is $-m_2$. Our problem then is how a contestant should choose a value of m , or, more precisely, whether there is a method of choosing m which is an ESS.

To answer this question, we need a more precise definition of an ESS. We define $E_J(I)$ as the expected pay-off to I played against J . Then I is an ESS if, for all J , $E_I(I) > E_I(J)$; if for any strategy J , $E_I(I) = E_I(J)$, then evolutionary stability requires that $E_J(I) > E_J(J)$. The relevance of the latter condition is as follows. If in a population adopting strategy I a mutant J arises whose expectation against I is the same as I 's expectation against itself, then J will increase by genetic drift until meetings between two J 's becomes a common event.

It is easy to show that no "pure" strategy (that is, no fixed value of m) is an ESS. Thus in a population adopting strategy m , a mutant adopting $m + \epsilon$ would always do better (and if $m > v$, a mutant adopting a zero strategy would also do better). It is, however, possible to find a mixed strategy which is an ESS. Let strategy I be a mixed strategy which selects a value of m between x and $x + \delta x$ with probability $p(x)\delta x$.

Then if

$$p(x) = (1/v)\exp(-x/v) \quad (1)$$

it can be shown that I is an ESS.

We conclude that an evolutionary stable population is either genetically polymorphic, the strategies of individuals being distributed as in equation (1), or that it consists of individuals whose behaviour differs from contest to contest as in (1). There is no stable pure strategy, and hence no behaviourally uniform population can be stable.

Conclusions

There are many complications left out of these simple models. The analysis is, however, sufficient to show that individual selection can explain why potentially dangerous offensive weapons are rarely used in intraspecific contests; a stable strategy does, however, require that contestants should respond to an "escalated" attack by escalating in return. Also, if contests are settled by a process of attrition, then evolutionary stability requires that the popula-

tion be genetically polymorphic, or that individuals vary their behaviour from contest to contest.

A more detailed analysis will be published elsewhere.

Ideas similar to those described here have been applied to human neurotic behaviour by J. S. Price¹⁸.

Lithospheric Plate Motion, Sea Level Changes and Climatic and Ecological Consequences

JAMES D. HAYS & WALTER C. PITMAN III

Lamont-Doherty Geological Observatory of Columbia University

We demonstrate quantitatively that the world-wide Mid to Upper Cretaceous transgression and subsequent regression may have been caused by a contemporaneous pulse of rapid spreading at most of the mid-oceanic ridges between -110 to -85 m.y. The rapid spreading caused the ridges to expand and hence reduced the volumetric capacity of the basins. The subsequent regression was caused by a reduction in spreading rates beginning at -85 m.y.

THE global nature of the great marine transgressions and regressions such as occurred in the Upper Cretaceous has been recognised for nearly a century¹. These fluctuations of sea level have been variously attributed to gradual filling of ocean basins by detritus displacing water onto the continents, down faulting of ocean basins to cause regressions¹ and simultaneous vertical movements of both continents and ocean basins^{2,3}. The transgressions and regressions have been linked to orogenic cycles; it has been argued² that during intervals of low orogenic activity reduced horizontal compression caused continental subsidence relative to sea level, hence transgressions, and that conversely orogenic episodes produced increased horizontal compression, increased continental elevation and marine regression⁴. Late Cainozoic sea level changes are certainly attributable to glaciation, but this cause is not applicable to the Upper Mesozoic.

Changes in the volume of ocean basins could explain flooding of portions of continental surfaces. It has been

proposed⁵⁻⁷ that such changes occur due to alterations in the volume of the mid-oceanic ridges. Valentine and Moores⁵ linked these volumetric changes to the assembly and breakup of super continents. Hallam⁸ speculated that the Upper Cretaceous transgression and regression may have been caused by a contemporaneous pulse of rapid spreading which substantially increased the volume of the world ridge system. We show that this latter proposal is correct.

Cause of Upper Cretaceous Transgression

The lithosphere formed at a spreading ridge axis is initially hot and therefore elevated; as it moves away from the axis, it cools and subsides^{9,10}. This cooling and subsidence is time dependent¹¹; the depth to which any portion of flanking-crust has subsided is essentially a function of age only. So one empirical age-depth relation fits most ridges regardless of spreading rate¹¹ (Table 1). Therefore, the volume of any ridge is a function of its spreading rate history and changes in the spreading rate cause, in time, changes in ridge volume. (It has been suggested that the axial portion of fast spreading ridges is deeper than that of slow spreading ridges¹¹; however, subsequent analysis has shown that this is not systematically true¹².) Larson and Pitman¹³ correlated anomaly lineations of Middle and Upper Mesozoic age in the Atlantic and Pacific. They calibrated these lineations with Deep-Sea Drilling Project data, thereby extending the magnetic polarity time scale to -160 m.y. From the geometry of these lineations they showed that during the Upper Cretaceous (-110 m.y. to -85 m.y.) there was an episode of rapid spreading in the central and south Atlantic and the Pacific. The geological evidence suggests an initial rise of sea level that began at or before the boundary between Upper and Lower Cretaceous (-100 m.y.), the cresting of this rise some time between the Turonian and Lower Maastrichtian (-90 and -70 m.y.) and a withdrawal that was most pronounced in the Maastrichtian but continued into the Cainozoic¹⁴⁻¹⁷.

Table 1 Empirical Values showing the Relationship between Crustal Age and Ridge Elevation¹¹

Age m.y.	Mean depth corrected (m)	Standard deviation (m)	No. of values	Mean depth at 5 m.y. intervals (m)	Elevation above 5.5 base level (m)

77	5,600	±63	13		

We use the Upper Cretaceous system of ridges proposed by Larson and Pitman¹³ (Fig. 2a, Table 3). In the Atlantic this system has not altered significantly since -180 m.y. except to extend both northwards and southwards. The Pacific ridges, however, are today different from the Cretaceous configuration¹³ (Fig. 2, a and c). For example, the lineations of Mesozoic age form a double magnetic bight indicating that a ridge-ridge-ridge triple junction must have existed at that time at points A and B of Fig. 2a. This system of ridges evolved into the present system (Fig. 2c). The Phoenix plate is now the Antarctic plate and Juan de Fuca, Cocos and Nasca plates are all that remain of the Farallon plate; the Kula plate is gone. The Galapagos Ridge (between the Cocos and Nasca plates) is no more than 10 m.y. old and does not affect our computations. Beginning at -75 m.y. there was a phase of spreading at about 3 cm yr⁻¹ between the small remaining eastern fragment of the Kula plate and the Pacific plate. (This event yielded the "Great Magnetic Bight of the North-east Pacific"¹⁸.) By -38 m.y. at the latest this spreading had ceased and the entire Kula plate with its bordering ridges had been subducted¹⁹. The volumetric increase due to this brief episode would have been small.

In calculating the volumetric changes for each interval, we have kept the length of each ridge segment fixed. In reality, the length of the ridges changed with time, but

Table 2 The Calculated Volume of the Ridge Segments at Various Times is Given as are the Changes in Total Volume and Sea Level

Data and Computations

We have computed the volume of most of the mid-oceanic ridge system at several times, beginning in the Cretaceous and extending to the upper Tertiary (Table 2). For each time and for each ridge segment an average cross-sectional area was computed using a standard age-depth curve¹¹ (Table 1). The data are referred to present day sea surface. Since sea level varies with time it is more meaningful to consider ridge volume in terms of elevation above an abyssal reference plain of 5,500 m. A history of spreading rates for the ridge segments is adapted from Larson and Pitman¹³ (Table 3).

Table 3 Lengths and Half Spreading Rates of Ridge Segments from -110 m.y. to -9 m.y.

we assume that as some ridges have grown in length an equivalent volume of other ridges has been subducted.

The Indian Ocean and Tethys Sea have been left out of our calculation. The spreading of the Indian Ocean is known in sufficient detail¹⁰ but since the Tethys is gone its history cannot be determined. As a first approximation we assume that as Tethys closed due to the drift of various Gondwana fragments into Eurasia, any ridge system that existed in Tethys gradually subsided, ridges and ridge axes were subducted. We also assume that this consequent volumetric decrease was about equal to the simultaneous volumetric increase in the ridges of the Indian Ocean.

To convert changes of ridge volume into changes of continental freeboard, we calculated isostatic adjustment due to increased water depth. If water depth increases by a thickness h , oceans subside a distance d . Assuming 3.3 g cm⁻³ for the density of the upper part of the mantle, $h=3.3d$ and the change in freeboard will be $(h-d)=0.7h$.

A second correction arises because the boundaries of the oceans are not vertical. As the oceans rise, more surface area is covered (Fig. 1). Approximately 1/6 of the Earth's surface ($85 \times 10^6 \text{ km}^2$) lies at elevations between 0 and +500 m (ref. 20). We assume that as sea level rises the area covered by the sea increases linearly ($0.170 \times 10^6 \text{ km}^2$ for each 0.001 km rise in sea level). Thus, the change in continental freeboard $(h-d)$ may be calculated from the equation

$$V = hA_0 + (0.7h)^2 170/2$$

Fig. 1 *a*, Schematic Upper Cretaceous two ocean ridge system. As spreading rates increase at -110 m.y. ridges expand horizontally causing a transgression by -85 m.y. Decrease in spreading rates after -85 m.y. causes ridges to contract and the seas to withdraw. *b*, As sea level rises from -100 m.y. (A) to -85 m.y. (B), sediments fill and level the inland seafloors. In contrast, as sea level lowers an equivalent amount between -85 and -70 m.y., the area of continent exposed is much greater (curve B to C).

where A_0 is the surface area of the ocean at -110 m.y. and $(0.7h)^2/170/2$ is the volume occupied by the sea encroaching on the continent. Hallam⁸, using the data of Termier and Termier²¹, shows that $33 \times 10^6 \text{ km}^2$ of presently emergent crust was covered by seas at -110 m.y. The present area occupied by the oceans is $359 \times 10^6 \text{ km}^2$; thus the oceanic area at -110 m.y. was $392 \times 10^6 \text{ km}^2$. The freeboard change ($h-d$) has been calculated from the equation for each cumulative total change in volume.

The values of ($h-d$) given in Table 2 have been computed relative to sea level taken as zero at -110 m.y. But since $33 \times 10^6 \text{ km}^2$ of the present day land area was covered by the seas⁸ at that time we estimate (using a standard hypometric curve²⁰) that sea level was about 100 m higher than today. The curve in Fig. 3 has been adjusted to give sea levels relative to the present.

Estimates of the late Mesozoic-Cainozoic changes in sea level computed from our model agree well with other estimates based on outcrops of marine sediments (Fig. 3). All except Termier and Termier²¹ place the time of the maximum transgression at about -85 m.y. Our curve indicates that sea level 10 m.y. ago was 40 m above the present stand. The total present continental ice volume, most of which accumulated during the past 10 to 20 m.y., is equivalent to 60 m of sea level change²². Therefore, our model predicts a present day sea level within 20 m of that observed.

Our estimates differ from those inferred geologically by others²¹⁻²³ in two respects (Fig. 3). First, we obtain higher sea levels during the maximum transgression. Our calculation may contain errors inherent in our assumptions but the corresponding geological estimates of past marine transgressions are based on the extent of Upper Cretaceous marine sediments, and hence are low, since 70 m.y. of erosion must have removed some of the Upper Cretaceous deposits⁷. Second, our model predicts that the rise of sea level during the transgression will occur at about the same rate as the fall during the regression.

Some geological data point to a more rapid regression than transgression. But it is likely that sedimentation led to the continuous filling and levelling of the epicontinental seafloors. Therefore, depths of the Cretaceous epicontinental seas in general would have been less than 500 m, perhaps only 100 to 200 m as suggested by the limited palaeontological evidence²⁴. Consequently, the area drained by the first 200 m drop of sea level would have been very large relative to the area flooded by the latest 200 m rise of the transgression (Fig. 1*b*). We estimate that between -85 m.y. and -60

m.y. sea level would have fallen by more than 250 m. This would have been sufficient to drain most continental areas and is in agreement with geological evidence.

Consequences of our Model

What is the relationship between tectonism, climate change and fluctuations in faunal diversity? We believe that our

Fig. 2 The extent of the seas for three geological epochs^{14,16,17,21}: *a*, Cenomanian (-100 to -94 m.y.); *b*, Santonian-Campanian (-70 to -85 m.y.); *c*, Eocene (-50 to -40 m.y.). The arrangement of the ridge axes at present is shown in *c*, where they are plotted with respect to North America.

model provides a working hypothesis to connect these phenomena. The effects of the Upper Cretaceous transgression and regression on climatic, stability, faunal diversity and ocean circulation (Fig. 4) are not necessarily newly discovered relationships. But we discuss them briefly to emphasize that all are related to changes in the rate of plate motion.

World climate: The uniformity and relative mildness of climate at the height of the Upper Cretaceous transgression are well documented²⁵⁻²⁷. An increase in the ratio of oceanic to continental area moderates and stabilizes climate⁴. This is because the heat capacity of water is very large compared with continental rocks or the atmosphere. With more than 40% of the continents covered by several hundred metres of water, this moderating effect must have been large. Also, the expanse of the epicontinental seas provided new corridors along which heat could be advectively transferred between low and high latitudes. Conversely, as the seas withdrew beginning in the Upper Cretaceous, continentality increased probably producing the well documented high latitude cooling and increased seasonal contrasts that continued through the Tertiary. This cooling trend leads to polar glaciation in the mid-Tertiary²⁸ and mid-latitude glaciation in the Quaternary. Palaeomagnetic data³⁶ demonstrate that the Arctic Ocean and possibly Antarctica had drifted to a polar position by the Upper Cretaceous^{30,36}. We therefore attribute these Late Cretaceous glaciations to continued fall of sea level (which caused increasing emergence of all continents, including Antarctica) and increased constriction of oceanic thermal advection between low latitudes and the Arctic Ocean. Post-Cretaceous opening of the North Atlantic did not significantly improve circulation with the Arctic because, as the Atlantic opened, routes to the Pacific closed³¹.

Fig. 3 Area of present day land covered by former seas plus the height of these seas above present levels plotted against age (adapted from ref. 8).

Ocean circulation: All available evidence suggests that the Upper Cretaceous oceans and their epicontinental seas were well mixed and productive in spite of the low thermal gradient between poles and equator. The pattern of circulation is not known, but it was probably quite different from that of the present.

Today the deep circulation of the oceans is maintained by high latitude formation of dense water in restricted seas or shallow shelf areas. We expect that a similar mechanism operated in the Upper Cretaceous and the source areas for deep and bottom waters lay in some of the epicontinental seas. With the withdrawal of the seas at the close of the Cretaceous some or all of these source areas may have been drained. New source areas would develop as the polar regions cooled but there may have been a short but important interval of stagnation as one regime of deep circulation was replaced by another. If a brief period of stagnation did occur there is no evidence that it led to the development of anaerobic conditions in any of the ocean basins.

Fig. 4 Proposed sequence of events causally related to an Upper Cretaceous worldwide increase in the velocity of plate motion and subsequent decrease.

Mesozoic-Cainozoic faunal crisis: The Upper Cretaceous stable and uniform climates allowed significant increases in diversity of many groups^{32,33}. The adaptation to these conditions produced an inherent vulnerability to change³⁴. We conclude that the marine withdrawal was most rapid between -70 m.y. and -60 m.y. because of isostatic rebound and sediment infilling of epicontinental seas (Fig. 1). Thus, in latest Cretaceous, the land area would have nearly doubled. The consequent environmental changes (increased thermal gradients and seasonal contrast^{33,35} and marked alteration of the ocean circulation and thermal regime) were probably equally rapid, producing stresses on species adapted to stable Upper Cretaceous conditions.

We acknowledge discussions with R. Batten, W. Broecker, A. Gordon, D. Hayes, M. Langseth, M. McKenna, and N. Newell.

Possibilities for the Evolution of the Genetic Code from a Preceding Form

THOMAS H. JUKES

Space Sciences Laboratory, University of California, Berkeley, California 94720

Analysis of the interaction between mRNA codons and tRNA anticodons suggests a model for the evolution of the genetic code. Modification of the nucleic acid following the anticodon is at present essential in both eukaryotes and prokaryotes to ensure fidelity of translation of codons starting with A, and the amino acids which could be coded for before the evolution of the modifying enzymes can be deduced.

THE sequences of nucleotide bases in genetic DNA and in the corresponding mRNA molecules store inherited information which is translated into polypeptide chains of proteins by an adapter mechanism. This involves pairing between anticodons in tRNA molecules; carrying specific amino acids, and codons in mRNA. The rules of pairing between tRNA and mRNA molecules result in the genetic code (Table 1). Alterations in the nucleotide sequences of tRNA molecules produce functional changes. Two of the functions of tRNA that can undergo such changes are codon-anticodon pairing, the site for which is located in the anticodon loop, and amino acid recognition, which, seems to be determined by various components of the tRNA molecule, perhaps including its tertiary structure. In some tRNAs the amino acid acceptor stem is involved in synthetase recognition¹, but this rule does not hold generally, and Loftfield¹ has concluded that amino acid recognition appears to be a property of the tRNA molecule as a whole, and cannot be ascribed to any particular sequence of bases in it.

The anticodon is a sequence of three nucleotides next in sequence to an invariant uridine in the anticodon loop. Mutational changes in the anticodon can take place that change codon pairing without affecting amino acid recognition². Such mutations result in the 'wrong' amino acid being placed in many polypeptide sequences, and may therefore be expected to be deleterious or lethal. tRNA molecules can also undergo changes in both the anticodon and the amino acid recognition function and such 'double

changes' can occur during evolution. This was discovered by Squires and Carbon³ who found that a glycine tRNA in *Escherichia coli* was similar to a valine tRNA isolated from the same organism with, of course, a different anticodon and different amino acid recognition function. Similarity, in excess of the similarity between all tRNA molecules for different amino acids, was also noted for lysine and arginine tRNAs occurring in yeast⁴.

Anticodon-Codon Pairing

In this article I develop the thesis that part of the evolution of the genetic code is brought to light by examining the nature of anticodon-codon pairing and by examining the four nucleotides that comprise the anticodon in tRNAs that participate in polypeptide synthesis on ribosomes and the nucleotide next following. This is always a purine nucleotide or its modification.

Ambiguity in the pairing between the first base of anticodons and the third base of codons (termed here, for convenience, '1-3 pairing') is responsible for a definite pattern in the genetic code⁵. The ordered ambiguity in 1-3 pairing was elegantly interpreted by Crick⁶, as shown in Table 2, in the cases of I, G, U and C in position 1 of anticodons. He proposed that these bases pair with three, two, two and one bases respectively in codons. Similarly, the base G in the third codon position will pair with both U and C in position 1 of the anticodon. Ambiguous pairing between position 2 of anticodon and codon does not exist and, with one exception to be discussed below, does not exist between anticodon position 3 and codon position 1 (3-1 pairing). Non-ambiguous 3-1 pairing takes place between A and U, and G and C. This may be attributed to conventional hydrogen bonding. Pairing between G and U is, however, known to take place in various RNA sequences without hydrogen bonding, and without displacing the helical structure of double strands of RNA⁶. This concept is basic to the understanding of 1-3 pairing. The ambiguity in base pairing between G with U and C, and U with A and G, potentially enables thirty-two anticodons to suffice for translation of all the codons for amino acids, for each pair of codons represented by NNU and NNC can bind with an anticodon GNN, 'read' in the reverse direction, and each NNA and NNG codon pair can bind with anticodon UNN (Table 1). In addition, there are anticodons that provide for duplicate translation of codons; for example, the anti-

a=Identified anticodons; *b*=codons.

The bases in anticodons are shown in unmodified form, except for I (inosine) which is a modification of A. The modifications are listed in Table 2.

Anticodons starting with G pair with codons ending in U and C; those starting with I pair with codons ending in U, C and A, and so on, as shown in Table 2.

codons UCC and CCC in glycine tRNAs both bind with the GGG codon for glycine.

Recent research by Nishimura and others (reviewed in ref. 7) has extended the pattern of ambiguity in 1-3 pairing. Uridine 5-oxyacetic acid in the first position of anticodons in certain *E. coli* tRNAs pairs with either U, A or G in the third codon position, and 2-thiouridine pairs only with A and not with G (ref. 7). Such modifications thus can either increase or decrease the ambiguity in 1-3 pairing. These enzymatic modifications of base 1 in anticodons vary in different organisms, and so have originated during the evolution of such organisms.

The presence of the invariant U preceding the anticodon would impose the minimum amount of steric hindrance to 1-3 pairing. This presumably facilitates pairing between modified bases at anticodon position 1 and codon position 3. Below, we shall contrast this with the effect of the modifications of the nucleoside following position 3 of the anticodon.

Table 2 First Base of Anticodons in Sequenced tRNAs compared with Third Base of Codons Paired

First base in anticodon	Pairing with	Organisms (E=eukaryotes, P=prokaryotes)	In tRNAs for

Abbreviations: H, hypoxanthine; I, inosine; oa⁵U, uridine-5-oxyacetic acid; Gm, 2'-O-methylguanosine; G⁺, 'Q-base' (an unidentified guanosine derivative); s²U, 2-thiouridine; U⁺, unidentified uridine derivative; ac⁴C, 4-acetylcytidine; Cm, 2'-O-methylcytidine; N, unidentified nucleoside; R, purine; Y, pyrimidine; fMet, N-formyl methionine; iMet=initiator methionine.

Adenine is absent in position 1 of anticodons. Adenine in this position is deaminated to hypoxanthine by a specific enzyme, adenine anticodon deaminase (ACD)⁸. Hypoxanthine, which is the base in the nucleoside inosine (I), pairs with U, C, and A (Table 2). Anticodons with I in position 1 can therefore exist for amino acids that have quartets of four codons that start with the same two bases (see, for example, the set of alanine codons in Table 1), but not for amino acids with two codons in a set (such as phenylalanine), because in the latter case, anticodons starting with I would transfer two different amino acids to the same codon. Anticodons starting with A, which should translate codons ending in U, therefore do not exist in living systems, and mutations that bring such anticodons into being in tRNAs for amino acids having two codons in a set are evidently discarded because the enzyme ACD presumably changes A in this position to I in any and all tRNA molecules. All tRNAs that have been sequenced which translate pairs of codons ending in pyrimidines have anticodons starting with G, when such pairs of codons are assigned to a single amino acid, provided that the corresponding pair of codons ending in purines is assigned to a different amino acid. This has been found so far for the tRNAs for Phe, Tyr, His, Asp and Ser (AGY codons).

Evolution of the Genetic Code

Various authors have advanced schemes for the origin of the genetic code based on proposals for direct affinity between amino acids and nucleotide bases or groups of bases. Such affinities are deemed to have played a part in the origin of life in the lifeless 'primitive soup'. The speculations are stimulated by experiments showing the formation of amino acids, purines and pyrimidines from mixtures of methane, hydrogen, ammonia, water, and so on, when treated with electrical discharge or ultraviolet radiation, as reported by Miller, Oro and others^{9,10}. The present genetic code, however, and presumably its immediate antecedents, involve the intervention of adapter molecules of tRNA which combine enzymatically with amino acids, rather than direct affinity between amino acids and nucleic acid molecules.

There are various possibilities for the composition of earlier codes. The number of amino acids coded may have been either more or less than twenty. Amino acids may have been added to the code during evolution or may have

disappeared. I have suggested that arginine displaced ornithine during the evolution of protein synthesis¹¹.

The idea that the number of amino acids in earlier codes was less than twenty is favoured by the fact that some of the 'simple' amino acids, such as serine, glycine and alanine, have four or more codons, and that the codons may be arranged in 'quartets', such as GCU, GCC, GCA and GCG for alanine, in which only the first two bases confer specificity on the amino acid. A code of 'quartets' of codons would suffice for not more than sixteen amino acids, and an arbitrary choice of 'newer' amino acids can be made¹² to reduce the present twenty to fifteen. Perhaps codons were not used for polypeptide chain termination. We shall now consider a different approach to identifying a smaller list of amino acids in the code, emphasising changes in anticodon-codon pairing.

Role of the Nucleotide following the Anticodons

Modifications in this nucleotide at RNA position 40 (ref. 13) are summarised in Table 3. The predominant pattern into which they fall shows that they are evidently concerned with establishing A-U and U-A pairing between the third anticodon position and the first codon position ('3-1 pairing'), occurring on the ribosome during polypeptide synthesis. These modifications enable the composition of a 'primitive' code for ten amino acids, six with eight codons and four with four codons, to be proposed.

Modifications at tRNA position 40 (Table 3) exist in both prokaryotes and eukaryotes. For 3-1 pairing between U and A, the modification in every known case consists of a bulky threonyl-containing side chain on position 6 of adenine. Presumably, these side chains serve, by steric

hindrance, to prevent pairing between U in the third position of the anticodon and G in the first position of the codon. The prevention of this pairing would be essential to fidelity of translation of all codons starting with A with the exception of *E. coli* tRNA^{Met}. This exception supports this hypothesis as follows: this tRNA initiates protein synthesis in *E. coli* by pairing with either AUG (the methionine codon) or GUG (a codon that normally is translated by valine). This tRNA has an unmodified A at position 40. Absence of the modification therefore permits 3-1 pairing by U with A or G and translation of either AUG or GUG as methionine. Uhlenbeck *et al.*⁶ examined the binding of GUG and a number of related oligomers by *E. coli* tRNA^{Met}. GUG and AUG had the same association constants with this tRNA. GUGA, which would bind with the sequence UCAU in the anticodon loop, had a much higher *K* than GUGU, suggesting that GUG in this oligomer was binding to the anticodon.

In the case of 3-1 pairing between A and U, the most common modification at position 40 is a bulky isopentenyl-containing side chain attached to adenine. An even more bulky molecular grouping, the large and complex 'Y-base', occupies position 40 in the eukaryotic phenylalanine tRNAs (for yeast, wheat and rabbit).

In the case of codons starting with U, it is essential that they should pair with anticodons ending with A and not with anticodons ending with G. These are anticodons for leucine (CUN codons), proline, histidine, glutamine and arginine (CGN codons). The nucleotide adjoining the anticodon in these tRNAs is methylated in prokaryotes (Table 3). Evidently, there is no 3-1 pairing between G and U, but always between G and C. Position 40 is often unmodified in tRNAs for amino acids with anticodons ending in C. This may be because there is no ambiguity in C-G 3-1 pair-

a, Anticodons; *b*, codons, showing anticodon-codon pairing in the first position of codons that includes ambiguity produced by pairing between G and U in addition to G·C and A·U pairing; (ii) code 2 is produced as a result of elimination of this ambiguity; (iii) present code resulting from changes in (ii).

ing, a result which would be consistent with the lack of ambiguity in C·G 1-3 pairing.

The pattern of modification at position 40 in the tRNAs of eukaryotes is less consistent than in prokaryotes. Perhaps eukaryotic ribosomes have assumed some of the functions needed for prevention of ambiguity. It is not known whether the initiator tRNA in eukaryotes pairs with GUG as well as with AUG.

All modifications of nucleotides in tRNA take place by enzymatic mechanisms following transcription. The evolutionary origin of the participating enzymes presumably antedated the prokaryote-eukaryote separation since, for example, t⁶A (Table 3) at position 40 occurs in all *E. coli* and yeast tRNAs that code for amino acids with codons starting with A. In an era before the evolutionary elaboration of these enzymatic modifications of position 40, 3-1 pairing in the ancestral prokaryotes would occur between U·G, and G·U as well as between A·U and U·A. Using only this assumption, and applying it to the present genetic code, an ancestral code results that contains eight codons apiece for each of six amino acids and four codons apiece for each of four amino acids (Table 4). It follows that the identity of these amino acids is such that their codons now start with C or G, and not with A or U. It is necessary, of course, to specify that each set of anticodons, or codons, can specify only one amino acid. As examples, the four codons for valine in the present code can be represented by GUN, pairing with anticodons represented by NAC. U·G pairing would, however,

codons NAU. These anticodons would pair also with the AUN codons. These must have been then assigned to valine, for the same set of anticodons would not specify two different amino acids. The initiator amino acid in protein synthesis by means of AUG and GUG codons would therefore have been valine.

The leucine codons CUN (Table 4) pair with anticodons NAG. The NAG anticodons will, however, also pair (G·U pairing in 3-1 position) with codons UUN, and these will also pair (A·U pairing) with anticodons NAA. Therefore, in this model, the CUN and UUN codons all coded for leucine.

The model for the ancestral code in Table 4 requires, for example, that proline, with anticodons NGG (pairing with codons CCN), should also have anticodons NGA, because NGG and NGA will both pair with codons UCN. Therefore UCN and CCN would be eight codons for proline. The codons with a middle A pose a special problem, for no amino acid has more than two codons with a middle A. It is therefore not possible to select, in terms of the present model, between histidine and glutamine, or between aspartic and glutamic acids, as to which member of each pair should be included in the ancestral code, so all four must be included. The procedure (Table 4, (i)) therefore leads to an ancestral code for ten amino acids.

These can be identified by their present codons all of which start with C or G. Arginine, for reasons advanced elsewhere¹¹, may have been preceded by ornithine. Therefore,

ancestral code. The inclusion of glutamine is surprising; this amino acid is formed enzymatically from glutamic acid. An alternative possibility is that all RUG, YUG, RUA and YUA anticodons belonged to histidine, and that the divergence between histidine and glutamine occurred during the later stage represented by Table 4 (ii).

It is of interest that yeast leucine-3 tRNA, with the anticodon CAA, pairing with UUG has 1-methylguanosine, that is, only a small side chain rather than an isopentenyl side chain, at position 40. This seeming anomaly is, however, consistent with the fact that specific distinction is not required between UUR and CUN codons, all six of which are for leucine (Table 4 (ii)). Therefore position 40 may have discarded 'bulky' modifications during the evolution of eukaryotic leucine tRNAs for pairing with codons starting with U.

The ten amino acids in the ancestral code would be adequate for the synthesis of proteins with reasonably versatile properties, except that the absence of serine is surprising. The list includes leucine and valine with hydrophobic side chains; the 'helix-breaker', proline; the two simple amino acids, alanine and glycine; histidine, which binds substrates and prosthetic groups; aspartic and glutamic acids, the acidic pair; a basic amino acid, ornithine; and glutamine, which is somewhat hydrophilic. According to the model, serine entered the code with eight codons, UCN and AGN, at the intermediate stage.

The expansion of the code to eighteen amino acids (Table 4 (ii)) was preceded by modifications of tRNA base 40, leading to the suppression of 3-1 pairing between G and U, and U and G. This enabled modifications of the amino acid recognition characteristics, by mutational base changes, to be adopted in tRNAs, so that 'new' amino acids entered

the process of protein synthesis, thus conferring novel and advantageous properties on proteins. Further expansion of the code to twenty amino acids then took place by other reassignments of tRNA molecules as summarised in Table 4 (iii). It is customary to postulate that a single species of organism, possessing the present code, displaced all other living organisms and proceeded, by divergent evolution, marked by gene duplication, allopatric speciation and natural selection, to give rise to various lines of descent that led to the existing terrestrial biota.

Satellite Observations of Intensity Variations of the Zodiacal Light

OBSERVATIONS of the intensity of the zodiacal light at 6530 Å have been made with a photometer on board the satellite D2A 'Tournesol'. This satellite was launched on April 15, 1971, from Kourou (French Guiana) into an orbit of inclination 46° with a perigee of 456 km and an apogee of 700 km. The spin axis was oriented towards the Sun with an accuracy of ~ 15 arc min and a spin period of 60 s (Fig. 1). The line of sight of the photometer is perpendicular to the spin axis and therefore scans the celestial sphere in a plane orthogonal to the ecliptic plane and to the direction of the Sun. Observations in a plane perpendicular to the Earth-Sun line (that is, at elongation $\epsilon = 90^\circ$ or $\epsilon = -90^\circ$) were carried out during the night phase, when the solar depression angle was $> 25^\circ$ and the altitude of the lowest observed points was > 135 km. Because of this, the signal contained no contribution from the night-glow, but was only due to zodiacal light and starlight. The data cover, without interruption, the period from April 19, 1971, to June 1973.

The photometer has been described previously¹. It has one channel at Balmer alpha (6563 Å), and a second at 6530 Å. Only 6530 Å data will be discussed here. The

bandwidth was 20 Å and the signal was integrated for $\frac{1}{8}$ s. Because of this integration time the field of view is extended from $1^\circ 20' \times 2^\circ 40'$ to $6^\circ 35' \times 2^\circ 40'$. A signal

Fig. 1 Line of sight of the photometer. A, $\epsilon = 90^\circ$, $\beta = 0^\circ$; B, $\epsilon = 90^\circ$, $\beta = 45^\circ$; C, $\epsilon = 90^\circ$, $\beta = 90^\circ$; D, $\epsilon = 90^\circ$, $\beta = 45^\circ$; E, $\epsilon = -90^\circ$, $\beta = 0^\circ$; F, $\epsilon = -90^\circ$, $\beta = -45^\circ$; G, $\epsilon = -90^\circ$, $\beta = -90^\circ$; H, $\epsilon = 90^\circ$, $\beta = -45^\circ$. ϵ is $\pm 1^\circ 20'$; β is $\pm 3^\circ 20'$.

of 100 S_{10} (vis) provides a count rate of ~ 670 counts s^{-1} , compared with a dark current of 60 counts s^{-1} outside the South Atlantic anomaly. A star takes two days to cross the field of view because of the rotation of the Sun-spacecraft line. This allowed us to demonstrate that after taking into account variations of sensitivity across the field of view, no sensitivity change could be detected. Furthermore, the on-board calibration source gave a signal that was constant within $\pm 5\%$. We therefore believe that no short term fluctuations of the instrument response occurred during the 2 yr of observation. The instrumental arrangement thus allows a measurement of the zodiacal light and its variation from day to day.

Table 1 Points Ignored in Editing Data

Moonlight (arbitrary units)	New Moon				Quar- ter Moon				Full Moon	
θ	0	1	2	3	4	5	6	7	8	9
(Line of view, Moon direction)	25°	25°	25°	30°	40°	50°	60°	60°	70°	70°
	180°									

All data relevant to a field of galactic latitude less than 30° , or containing a known star of magnitude brighter than +6 or corresponding to the simultaneous observation on the 6563 Å channel of an HII region or of a non-nominal geocoronal Balmer α emission have been removed from this analysis. All points less than an angle θ from the Moon, given in Table 1, together with the Lagrangian points of the Earth-Moon system have also been removed. After this editing of the data, the recorded signal N was generally between 600 and 3×10^3 counts s^{-1} . The zodiacal light intensity is $I = (N - n)c/20 - h(I^{\text{II}}, b^{\text{II}})$ where n is the dark current, c the absolute calibration coefficient and $h(I^{\text{II}}, b^{\text{II}})$ the integrated starlight contribution² as a function of galactic coordinates. Two consecutive years of data have already been reduced.

Fig. 2 Typical example of the 6530 Å intensity as a function of the ecliptic latitude β for May 25, 1971.

Figure 2 shows a typical example of the 6530 Å intensity measured as a function of the ecliptic latitude β for May 25, 1971. The measurements were taken over four nocturnal parts of orbits and about sixty rotations of the satellite around its axis. The intensity has two maxima as the line of sight intersects the ecliptic plane and two minima in the direction of the ecliptic poles. The small scatter of the data allows an intensity of the zodiacal light to be measured quite accurately. As was found using OSO-2 satellite data³ the zodiacal light intensity remained constant during successive orbits on one day.

Fig. 3 Variation of the intensity of the zodiacal light. 1, November 4, 1971; 2, November 6, 1971; 3, November 7, 1971; 4, November 10, 1971; 5, November 12, 1971. Full Moon on November 2, 1971.

The intensity of the zodiacal light was sometimes observed (contrary to other satellite observations^{4,5}) to vary from one day to the next. Figure 3 shows an example of the variation of the intensity as a function of ecliptic latitude from November 5 to November 11, 1971. There was an increase of about 100% in the intensity for negative elongations, compared with the values on November 4 and November 12, while for the positive elongations it remained constant. To check whether the enhancements of the intensity were due to an asymmetry in the observations, measurements on November 4 were compared with those on November 7 under the same conditions: spacecraft latitude $\sim 45^\circ$, local time near midnight, no stray emissions, line of view above the horizontal plane of the spacecraft, and galactic latitudes comparable. Under those conditions, the enhancement was $\sim 100\%$.

Table 2 Comparison with Previous Measurements

β	Zodiacal light intensity at 90° elongation (S_{10} (vis))			
	Roach <i>et al.</i> ⁶	Dumont ⁷	Lillie ⁸	Our results
0°	250	202 to 170*	180	150 ± 10
45°	140	90 to 62*	75	75 ± 5
90°	110	65 to 50*	50	57 ± 5

* Lowest values.

To study the annual variation, the mean value of the intensities for eight directions (Fig. 1) (in the ecliptic plane, towards the ecliptic poles and at $\pm 45^\circ$ latitude) was computed for each day. The r.m.s. value was about $7S_{10}$ (vis). The number of measurements in each field is about fifteen, and the removal of a large proportion of data (to avoid stray emissions) is responsible for the fact that the eight mean values do not exist simultaneously on Fig. 4. When there is no increase, our results are in good agreement with previous measurements as is shown in Table 2. The main features of the data are the increases in intensity of up to 100% in a few days with a time constant of 3 to 25 d. The increases do not always appear simultaneously in all directions but may occur over a limited part of the sky.

The observations at the ecliptic poles are of considerable interest. Figure 5, which represents two consecutive years

Fig. 4 Mean value of the intensity for eight directions (see Fig. 1). *a*, $\varepsilon < 0$: +, ecliptic plane (E); O, $\pm 45^\circ$ latitude (D, F); ●, south pole (G). *b*, $\varepsilon > 0$: +, ecliptic plane (A); O, $\pm 45^\circ$ latitude (B, H); ●, north pole (C).

of data, shows parallel trends of the evolution with time of the ratio of polar intensity to the intensity at 45° , and definitely proves that the variations of the zodiacal light are correlated with the position of the Earth in its orbit.

These variations may explain why the brightness of the zodiacal light is uncertain⁹ by a factor of ~ 2 . The large value of the variations and their dependence on angle of sight rule out an effect of the solar wind or of the solar activity.

In the example presented in Fig. 3, a 100% increase in intensity was observed near the ecliptic plane on November 7 and there was an enhancement of more than 50% for 6 d around the maximum. The Earth might not at that time have been far from the debris of comet Biela (Andromedids), the inclination of which to the ecliptic is 6° .

On April 21, an increase of 50% was observed in the polar and 45° directions and the half enhancement (25%) had been detected for 4 d. During this period the Earth encountered the Lyrids, the debris of comet 1861-I, the inclination of which is 80° .

It thus seems that the zodiacal light fluctuation by a factor of 2 is due to the scattering of solar light by local streams of particles. The variations in the increases as a function of angle to the ecliptic poles depend on the orbits of the particles. The magnitude of the increase would seem to indicate that the zodiacal cloud consists of a collection of such streams created on account of the Poynting-Robert-

Fig. 5 Observations at the ecliptic poles in two consecutive years. O, April 1971 to March 1972; +, April 1972 to March 1973. *a*, North pole side; *b*, south pole side.

son effect by rather recent comets with a short lifetime. The interweaving of these elliptic toruses mainly constitutes the zodiacal cloud.

New Galactic Supernova Remnants

We have identified twenty-seven galactic radio sources as supernova remnants by comparing 408 MHz observations from the Molonglo radio telescope and 5,000 MHz observations of comparable resolution from the Parkes 64-m radio telescope. The distribution of these and other supernova remnants with positions estimated from a new surface brightness-linear diameter relation has been investigated for evidence of galactic spiral structure.

Most extended non-thermal radio sources close to the galactic plane have morphological and spectral characteristics similar to those of the unambiguously identified galactic supernova remnants, and are consequently also considered to be supernova remnants (SNRs). These characteristics include: (i) a non-thermal radio spectrum, due to radiation by the synchrotron mechanism invoked to describe radio emission from SNRs; (ii) where resolution permits such recognition, a 'ring' or 'part-ring' radio brightness distribution indicative of an expanding shell source.

Within the region surveyed, seventy sources have previously been classified as SNRs (see ref. 1). Therefore the new observations represent a significant increase in the number of galactic SNRs observed at southern declinations, and in particular of older low surface brightness remnants for which previous lists were incomplete.

Green² has completed a high resolution 408 MHz galactic survey using the Molonglo telescope, which has a beamwidth of $2.86'$ in right ascension by $2.86'$ (zenith angle) in declination. The region with new galactic coordinates $|b| < 3^\circ$ and $l \ 195^\circ - 360^\circ - 55^\circ$ was observed. Because at 408 MHz non-thermal radiation predominates, the survey proved particularly useful for work on SNRs.

We prepared a list of those extended galactic sources from the Molonglo survey which had not previously been classified on the basis of their spectra and structure as HII regions, SNRs, or extragalactic radio sources. A cursory estimate of the spectral index was obtained using the 2,700 MHz flux densities from the Parkes survey (see ref. 3 and references therein); however, accurate spectral indices can best be obtained from investigations at two widely different frequencies with similar beamwidths. Accordingly, some seventy sources

which had been noted by Green² as worth investigating as possible SNRs from the 408 MHz–2,700 MHz comparison in the range l 260°–345°, plus some additional suspects outside this range, were observed with the Parkes 64-m radio telescope at 5,000 MHz (half-power beamwidth ~ 4 arc min). From the 408 MHz–5,000 MHz comparison we have been able to derive accurate positions, flux densities, spectral indices, and angular sizes for twenty-seven of these sources believed to be SNRs. Brightness temperature contour maps for the sources are in preparation, and will be presented separately.

For the 408 MHz observations the flux density scale used was that of Wyllie⁴. During each observing session several standard sources selected from Hundstead^{5,6} were measured for calibration purposes. At 5,000 MHz the system was calibrated using Hydra A for which a flux density $S(5,000 \text{ MHz})$ of 13.5 f.u. was assumed.

The derived parameters for the new remnants are given in Table 1, which includes the galactic source number ($l-b$), the equatorial coordinates (1950), the mean angular diameter and the flux densities and spectral index estimate for each source. The mean angular diameters $\langle \phi \rangle = (\phi_{\text{RA}} \times \phi_{\text{Dec}})^{1/2}$ were estimated from the outer radio isophotes used to determine the limits of integration in the estimation of the flux densities, and not from the half-power levels often used. The spectral index α is defined by the simple power law $S_\nu \propto \nu^\alpha$, where S_ν is the flux density at frequency ν . The flux densities for both 408 MHz and 5,000 MHz observations have errors due to noise and calibration uncertainties of less than 5%. The corresponding error in spectral index may be greater in confused regions where the extent of the source is not clearly defined. In such cases particular care was taken in defining the extent of integration. Sources with relatively flat spectra have been retained only where a thermal spectral index of -0.1 is believed to lie outside the range of possible errors. To exclude extragalactic objects, sources with relatively steep spectra have been excluded unless they show a shell structure.

Some properties of individual sources are as follows:

G321.9–0.3. This SNR extends into the error box of the Uhuru X-ray source⁷ 2U1516–56. But since the X-ray source is pulsating it is unlikely that the SNR itself is the origin of the X-ray emission.

G323.5+0.1. Since this non-thermal source is confused at 5,000 MHz with a neighbouring HII region, it has only been possible to place limits on the 5,000 MHz flux density.

G335.2+0.1. The proximity to the X-ray source 2U1624–49 may be worth further investigation.

G339.2–0.4. Although the spectrum of this source is not as steep as average ($\alpha_\nu = -0.48$) it seems to be non-thermal and has a part-shell structure. Its proximity to the X-ray source 2U1641–45 and the recently discovered Parkes pulsar 1641–45 is of interest.

If the relation between surface brightness Σ and linear diameter D for SNRs at known distances is established, the distances and galactic distribution of all others may be investigated if they are treated as being identical. Representing the relation as $\Sigma \propto D^{-n}$, earlier investigations of galactic SNRs have yielded empirical values of n in the range 2.7 (at 400 MHz, ref. 8) to 4.5 (at 1,000 MHz, ref. 1). Spectral and evolutionary differences, as well as observational errors, would be expected to have contributed to the uncertainty in n .

Mathewson and Clarke⁹ used fourteen SNRs detected in the Magellanic Clouds to establish the relation

$$\Sigma_{408} = D_{\text{pc}}^{-3} 10^{-15} \text{ W m}^{-2} \text{ Hz}^{-1} \text{ sr}^{-1}$$

This relation has the advantage that the distance of all the calibrators is reliably known, whereas for many of the galactic calibrators uncertainties in their distances of up to 50% exist. But as noted by Mathewson and Clarke⁹ the Magellanic Cloud SNRs seem to be inherently brighter objects than galactic SNRs of the same linear diameter.

In view of the uncertainties in earlier galactic Σ – D relations, and the apparent difference between Galactic and Magellanic Cloud SNRs, the galactic Σ – D relation has been rederived. The distance calibrators used were those class 1 and class 2 calibrators listed by Ilovaisky and Lequeux¹⁰ with surface brightness values in the range 3×10^{-21} to $3 \times 10^{-19} \text{ W m}^{-2} \text{ Hz}^{-1} \text{ sr}^{-1}$, this being the range over which we wish to apply the relation for distance determination. (We note that this excludes Cas A, the Crab, and Cygnus Loop.) The surface brightness results for the southern sources were calculated from the Molonglo survey.

Table 1 Parameters for the 'New' Remnants

Galactic source number	Position ($\sim$ centroid)		Mean angular diameter $\langle \phi \rangle$ (arc min)	Flux densities (f.u.)		Spectral index α	Distance d (kpc)	Displacement from galactic plane z (pc)

Fig. 1 Galactic neutral hydrogen map of Kerr¹¹, with SNR positions superimposed. The new SNRs are indicated by circles, and those from Woltjer¹² by crosses.

The data are well fitted by either of the expressions

$$\Sigma_{408} = 0.7 D_{pc}^{-3.0} 10^{-15} \text{ W m}^{-2} \text{ Hz}^{-1} \text{ sr}^{-1} \quad (1)$$

or

$$\Sigma_{408} = D_{pc}^{-3.11} 10^{-15} \text{ W m}^{-2} \text{ Hz}^{-1} \text{ sr}^{-1} \quad (2)$$

In expression (1) the Mathewson and Clarke exponent was retained. The difference in surface brightness could then indicate, as Mathewson and Clarke suggest, a mean initial energy for the Magellanic Cloud SNRs about 25% greater than that for galactic SNRs. In expression (2) the data were fitted retaining the Mathewson and Clarke proportionality constant and altering the exponent to fit the data, which might indicate a difference in evolutionary behaviour. But the difference in distance estimates for the two expressions over the Σ range of interest is less than 3%. We have arbitrarily adopted expression (1) for our subsequent calculations. SNR distance estimates thus obtained are about 10% less than those obtained using the Mathewson and Clarke relation, but somewhat greater than distance estimates obtained using earlier Σ - D relations. The distance estimates d , and displacement from the galactic plane z , for each of the newly discovered SNRs are included in Table 1.

The galactic distribution of the new SNRs catalogued in Table 1 is shown in Fig. 1 superimposed on the neutral hydrogen spiral arm map of Kerr¹¹. Kerr shows the two major arms within the solar circle (the Sagittarius and Norma-Scutum arms) as only roughly defined in view of the uncertainties in kinematic distances for this region. The position estimates of the new SNRs are indicated by circles. Also included on the diagram and indicated by crosses are the position estimates found using the new Σ - D relation, of the well known SNRs catalogued in Tables 1 and 3 of Woltjer¹² (with the exception of G8.5-0.3, which has been shown to be thermal¹³). The Crab, Cas A, and the Cygnus Loop are not included in the diagram since they have surface brightness values outside the limits used in deriving the Σ - D relation. SNRs with $|z| > 250$ pc have also been excluded from the diagram. Flux densities used in the distance calculations for the southern sources were taken from the Molonglo survey, while for those sources north of declination $+19^\circ$ data were taken from Woltjer¹².

The SNR distribution exhibits certain features similar to the HI distribution. Most of these SNRs lying between the Sun and galactic centre appear to lie on the inner spiral arms. The group of SNRs approximately 3 to 4 kpc from the galactic centre may indicate the position of the inner expanding arm (shown as dashed in Fig. 1).

More reliable distances for known SNRs are desirable in order to investigate the intrinsic dispersion of the Σ - D evolu-

tionary curve, and to see whether the technique of using SNRs as spiral arm tracers can be pursued further.

We thank Professor B. Y. Mills and Dr B. J. Robinson for arranging this joint investigation. The Molonglo Radio Observatory is supported by grants from the Australian Research Grants Committee, the Sydney University Research Grants Committee, and the Science Foundation for Physics within the University of Sydney.

Are Large Time Differences in Meteorite Formation Real?

In recent years two types of cosmochronological dating have been interpreted to indicate that there are large time intervals, a few times 10^7 yr, between the formation of various meteorite samples. For example, extrapolation backwards along isochrons in seven basaltic achondrites led Papanastassiou and Wasserburg¹ to establish a 'standard' initial $^{87}\text{Sr}/^{86}\text{Sr}$ ratio of 0.69898 ± 0.00003 (BABI ≡ 'basaltic achondrite best initial'). Similar isochrons in another basaltic achondrite, Angra dos Reis, led, however, to an initial ratio of 0.69884 ± 0.0004 (ADOR ≡ 'Angra dos Reis')². The difference between these two values is attributed to the accumulation of different amounts of the ^{87}Sr decay product of ^{87}Rb . If this reflects a difference in the times of fractionation between Rb and Sr in the meteoritic material, then the time interval is 14×10^6 yr. More recently, Tatsumoto, Knight, and Allegre³ found significant differences in the radiogenic $^{207}\text{Pb}/^{206}\text{Pb}$ ratios in Angra dos Reis and in two other basaltic achondrites, the value for Angra dos Reis being 0.6197 and the average of the other two being 0.6081. These nuclides result from the decay of ^{235}U and ^{238}U . If the differences are attributed to different times for the events of lead-uranium fractionation in the meteoritic materials, then the indicated time interval is 27×10^6 yr.

Are these time differences real? Or were there significant isotopic abundance variations in different parts of the primitive solar nebula in which different meteorite samples accumulated?

These questions are of obvious importance in establishing boundary conditions on the history of the Solar System. I present here a case for the second alternative and suggest experiments to settle the issue.

The isotopic composition of the heavier elements can vary if there is a variable ratio of s-process products to r-process products. These have different astrophysical sources. The s process probably takes place in stars somewhat more massive than the Sun while they are in their more advanced stages of evolution in the red giant region of the Hertzsprung-Russell diagram⁴. The products are probably ejected into space relatively gently in stellar winds or as parts of planetary nebulae; they cannot withstand unaltered the severity of a supernova environment. The r process probably occurs in the envelopes of type II supernovae when the high ion temperature precursor of the shock wave becomes strong enough to cause helium spallation, with copious neutron formation and ultimate production of deuterium⁵⁻⁷. The presupernovae of type II seem to be stars of at least $4 M_{\odot}$. In the following discussion I shall assume that the s-process products are uniformly distributed in space; to the extent that this may not be true, the effects discussed will be amplified.

Reeves⁸ has recently applied the analysis of Spitzer⁹, of the slowing down of supernova debris through interaction with the interstellar medium, to a discussion of the thoroughness of the mixing of the supernova products throughout the interstellar medium. A type II supernova will probably interact dynamically with about $10^4 M_{\odot}$ of gas in slowing down in about 10^6 yr. Reeves assumes that the supernova nucleosynthesis products are intimately mixed with this material, and that mixing with additional material will continue during the course of a few more million years as a result of random motions of the gas. On this basis he concludes that any typical part of the gas will be contaminated with fresh supernova debris every few million years, and that the isotopic composition of the interstellar medium will be maintained the same over a large local volume of the Galaxy.

This analysis does not, however, take into account the effects of the interstellar magnetic field. Even in typical neutral hydrogen clouds the magnetic field is effectively tied to the gas because of ions produced by ultraviolet radiation. Some mixing of supernova debris across field lines may take place as a result of short-scale dissipation processes, particularly during the early part of the supernova envelope expansion. A typical type II supernova explosion is likely to eject only a few solar masses of material, and this may perhaps be mixed into only about $10^2 M_{\odot}$ of the $10^4 M_{\odot}$ which participate in the dynamics of the slowing down process. Because of the operation of Rayleigh-Taylor instabilities, the supernova debris is likely to end up in the form of many thin tubes of magnetic flux threading through the much larger amount of material which has participated in the dynamical deceleration. Subsequent mixing would be mainly confined to longitudinal diffusion along the field lines, a very slow process.

There are about $10^{10} M_{\odot}$ of gas in the Galaxy, and about one type II supernova explosion per 10^2 yr. Thus it may be that any given part of the interstellar medium has received a direct injection of the debris from only about one of these supernovae.

Processes do, however, exist which should ultimately lead to complete mixing of material. Material in very dense interstellar clouds is shielded from ultraviolet light, so that significant drifting across field lines may occur, particularly for elements with higher ionization thresholds. Under these circumstances, heavier atoms can also adhere to interstellar grains, which can drift across field lines more easily than ions. Occasionally interstellar material will participate in a star formation event, in which $\sim 10^4 M_{\odot}$ collapse to high density with fragmentation to form stars in what become expanding associations. The condition that a newly-formed association of stars should be unbound is that more than half of the collapsed mass should be ejected, presumably as gas which never

became part of the stars. Since the interstellar magnetic field can slip out of the collapsing gas¹⁰ when the density exceeds 10^6 atoms cm^{-3} and since the collapsing gas is likely to be turbulent, thorough mixing will occur at that time. Truran and Cameron¹¹ have estimated that about half the interstellar medium had been through stellar interiors at the time of formation of the Solar System. From these various considerations I estimate that the products of stellar nucleosynthesis probably become homogenised in the interstellar medium after about 3×10^9 yr, but that more recent products remain localised in thin tubes of magnetic flux.

Although it seems that the production of the more abundant lighter elements was concentrated toward the early history of the Galaxy, the s and r processes are of secondary and tertiary character, transforming previous products of nucleosynthesis. Thus for the present purposes it is sufficient to suppose that the heavy elements have had a uniform production rate throughout galactic history. Thus at the time of formation of the Solar System, the interstellar cloud complex which was about to collapse probably had about 80% of the heavy elements uniformly distributed throughout the mass, on which was superposed a highly local fluctuation in abundance of the order of 25% of the average abundance.

During the collapse, turbulent mixing would tend to reduce these local fluctuations¹². After fragmentation, the gas would settle into differentially rotating flattened gaseous disks, which would then dissipate to form stars. Differential rotation would tend to homogenise composition at any given radius, but some small radial composition differences might persist. This might be the source of the strontium isotopic differences characteristic of BABI and ADOR, and the related lead-lead differences. In the following I assume that there was a fractional difference of Δ in the r-process abundances in BABI and ADOR, and enquire what effects this would have on strontium and uranium isotopic abundances.

The strontium case is actually very complicated. ^{86}Sr and ^{87}Sr are s-process isotopes, except for the small leakage of the r process to the latter through ^{87}Rb , which has a half-life four times the age of the Galaxy. Because mass spectrometers sometimes suffer from mass fractionation problems in the ion source, however, the common practice is to refer the abundance of ^{87}Sr to the slope of abundances between ^{86}Sr and ^{88}Sr . The latter isotope has both s and r-process components. Furthermore, the s-process neutron capture path passes through ^{85}Kr , which has a half-life of 10.76 yr. A recent analysis by Scalo and Ulrich⁴ indicates that the s process may occur in a series of relatively short neutron bursts. So the s-process path probably divides at ^{85}Kr , producing both ^{86}Sr and ^{86}Kr . By itself, this may introduce some fluctuations in the $^{87}\text{Sr}/^{86}\text{Sr}$ ratio, but I shall ignore this complication here. One cannot, however, take the abundance of ^{86}Kr as indicative of the local r-process abundance.

The other neighbouring r-process-only isobars are ^{82}Se , ^{96}Zr and ^{100}Mo , with abundances of 6.18, 0.784 and 0.385, respectively, on an abundance scale¹³ where silicon = 10^6 . An interpolation suggests the r-process abundance contribution to ^{88}Sr to be about 2.5 out of a total abundance of 22.2. A fractional abundance fluctuation Δ in this contribution would thus produce a fluctuation $0.5 (2.5/22.2) \Delta = 0.056 \Delta$ in the $^{87}\text{Sr}/^{86}\text{Sr}$ ratio that would be inferred from analysis of mass spectrometer measurements. The fractional difference between BABI and ADOR of 2.0×10^{-4} would thus imply $\Delta \approx 3.5 \times 10^{-3}$. This estimate must be regarded as uncertain by a factor three. Nevertheless the fluctuation represents a reduction by two orders of magnitude from the local fluctuations that may have characterised that part of the interstellar medium which collapsed to form the Solar System.

The analysis of the uranium isotopes must be even cruder because of their radioactive character. The fractional abundance of a radioactive isotope, relative to the total amount ever formed, is the ratio of its mean life to the total time needed to accumulate a non-radioactive nuclide at the recent production

rate. The mean life of ^{238}U is 6.4×10^9 yr, or twice the time required for homogenisation of abundances. The homogenised background of this nuclide may thus be about 50% of the total, with local fluctuations in abundance of the order of a factor two. The mean life of ^{235}U is 1.02×10^9 yr. The homogenised background abundance level is thus only about 4% of the average, and local fluctuations may be an order of magnitude about the mean. There will be some correlations between the abundance fluctuations of ^{235}U and ^{238}U . I estimate the fluctuations that may occur in the radiogenic $^{207}\text{Pb}/^{206}\text{Pb}$ ratio to be of order 20Δ , but not even the sign of these can be predicted, because a region with excess r-process production might or might not have had a recent contribution within the homogenisation time, and thus the ^{235}U might be high or low when there is an r-process excess.

For what it is worth, the difference in $^{207}\text{Pb}/^{206}\text{Pb}$ ratios between Angra dos Reis and the other two basaltic achondrites implies an order of magnitude $\Delta \sim 0.019/20 \sim 10^{-3}$. Since in this case it seems that ^{235}U is in excess in Angra dos Reis, it is perhaps not surprising that this meteorite also has a large component of the fission decay products of ^{244}Pu , an extinct radioactivity with a half-life of 82×10^6 yr (ref. 14).

Thus it seems that a case can be made that the isotopic differences between Angra dos Reis and other basaltic achondrites may be due to real fluctuations between the relative abundances of s-process and r-process nucleosynthesis products at a level $\Delta \sim 10^{-3}$. These differences are at a level which is subject to detection by careful mass spectrometry. The optimum ranges of elements in which to seek such effects are those in which there are comparable abundances from the two processes. Elements of even atomic number in the range from germanium to tellurium are probably most suitable for these measurements. If such differences should be found, this would provide a new tool for finding difference source regions in which Solar System materials have accumulated.

After this letter was submitted, I learned of the important work of R. N. Clayton, L. Grossman, and T. K. Mayeda (personal communication) showing that individual minerals in carbonaceous chondrites contain variations in oxygen isotope ratios that must represent different mixtures of separate nucleosynthetic processes. The general theoretical considerations given here should also provide an explanation of these effects.

Post-depositional Remanent Magnetisation in Deep-sea Sediment

SEDIMENTS of various lithologies cored from most parts of the deep ocean floor have been found to contain a record of the past behaviour of the Earth's magnetic field, especially the sequence of reversals over at least the past 5 m.y. (ref. 1). The mechanism by which these sediments acquired their natural remanent magnetism (NRM) is, however, still poorly understood. We have recently conducted experiments that indicate that post-depositional remanent magnetisation² is a viable mechanism of magnetisation of deep-sea sediments.

Laboratory studies of the most obvious mechanism, depositional or detrital remanent magnetism (DRM), have shown that the remanent inclination is usually shallower than the field inclination in which the sediment was deposited^{3,4}. The difference is thought to be due to the effects of gravity overcoming magnetic-orienting couples of the magnetised grains at the instant of deposition⁵. The NRM inclinations of deep-sea sediments generally agree, however, with the expected axial dipole field inclinations⁶. It has been suggested⁷ that these sediments may acquire their remanent magnetism shortly after deposition, by the post-depositional mechanism observed in synthetic sediment². The physical origin of this remanence is likely to be closely related to Brownian motion⁸. In deep-sea sediments, a remanence may be acquired as a result of sediment disturbance by benthic organisms⁹. The natural remanent magnetism of some sediment may also be of chemical origin as a result of *in situ* authigenic growth of ferromagnetic minerals¹⁰.

Deep-sea sediment was obtained from the bottom of a Lamont core, RC14-14, the magnetic properties of which have been reported¹¹. The NRM was of a stable type; alternating fields necessary to randomise 50% of the original NRM (median destructive fields) averaged 200 oersted. The average magnetic inclination of the core was not significantly different from the axial dipole field inclination at the core site. The dominant magnetic minerals were essentially magnetite and titanomagnetite (compositional parameter, $x=0.53$) which were incorporated in a matrix of diatomaceous clay.

A quantity of the sediment was thoroughly dispersed in a sufficient amount of distilled water to form a thick slurry,

Fig. 1 Inclinations of the control field and the remanent magnetisation of the reconstituted sediment. Error bars represent range of remanent inclinations for each sample; the line of perfect agreement is shown. Successively steeper inclinations were produced in fields of 0.20, 0.28, 0.38, 0.59 and 1.20 oersted, respectively.

Fig. 2 Intensities of the control field and the remanences of the reconstituted sediment, before (+) and after (Φ) 100 oersted a.f. demagnetisation. Regression line slopes are 5.96 ± 0.19 ($\times 10^{-4}$ gauss oersted $^{-1}$) and 3.87 ± 0.20 ($\times 10^{-4}$ gauss oersted $^{-1}$), respectively. ■, Average remanent intensity of RC14-14, after 100 oersted a.f. demagnetisation¹¹, plotted against the present axial dipole field intensity at the core site.

similar in consistency to that normally found near the tops of piston cores immediately after coring. The sediment slurry was spooned into plastic cylinders (diameter 7 cm, height 5 cm) that had perforated bottoms covered with paper towelling to prevent sediment loss. Helmholtz coils were used to provide various field intensities and directions. The sediment slurry was thoroughly stirred in the presence of a known field and allowed to dry in this same field. Two or three specimens were cored from each sample with a plastic cylinder after the sediment became cohesive yet not completely dry (generally after 4 to 7 d). The remanent magnetism of each specimen and that remaining after partial alternating field (a.f.) demagnetisation¹² were measured with a slow-spin magnetometer. Unreliable results were obtained if the sediment was too wet.

The remanent inclinations agreed reasonably well with the inclinations of the control fields (Fig. 1). No systematic deviation of the remanent magnetism direction from that of the control field, such as inclination error^{4,13}, was observed. The scatter of directions among specimens from an individual sample is attributed chiefly to specimen orientation errors and, more important, to visible deformation of the sediment resulting from partial desiccation.

The remanent intensity was linearly proportional to the intensity of the control field, at least up to 1.2 oersted (Fig. 2). The regression line through either the remanent intensities or the partially demagnetised remanences intersects the ordinate at a value not significantly different from zero magnetisation intensity. Only 35% of the remanence was randomised by 100 oersted a.f. demagnetisation as illustrated by the different slopes of the two lines. Alternating field demagnetisation curves of individual specimens show median destructive fields of about

200 oersted, with corresponding directional changes of less than 10° .

The process of stirring the sediment in the presence of a magnetic field may be analogous to the activities of benthic organisms at, or just beneath, the sediment-water interface on the ocean floor¹⁴. Core RC14-14 shows evidence of benthic organism activity or bioturbation over most of its length¹¹. The NRM of the core and the remanence of the reconstituted sediment are similar in intensity (Fig. 2), in stability against alternating fields and in their apparent lack of systematic inclination error. This evidence suggests that the stable NRM is a post-depositional remanent magnetisation acquired in conjunction with physical disturbance by benthic organisms in most sections of the core.

Mixing of deep-sea sediment by benthic organisms is seen from photographs to be a common feature of the ocean bottom environment¹⁵ and evidence of it is found in many sediment cores^{16,17}, which often contain good magnetic records^{18,19}. Therefore, a substantial portion of deep-sea sediment may have acquired an NRM as a result of a sediment-mixing process. This is not to say that mixing is a prerequisite for the acquisition of post-depositional remanence in sediment. Preliminary results show that the same sediment acquires a stable remanence in the direction of an applied field without stirring. It has no inclination error but has a somewhat lower intensity. Even if the DRM mechanism is also a factor in the original magnetisation of deep-sea sediment, realignment of this type of remanence may occur after deposition. The small grain diameters of magnetic minerals often encountered in deep-sea sediment (generally $40\% < 1 \mu\text{m}$)²⁰, coupled with the field dependence and lack of inclination error of this post-depositional remanence, support the Brownian motion model of magnetic grain alignment in a field in the sediment^{8,21}.

The extent to which the sediment and its observed remanent magnetism are contemporaneous must vary with depth of faunal activity and other factors controlling the immobilisation of magnetic grains in the sediment. These include grain size, grain magnetic moment and sediment-water content. The mean burrowing depths are apparently only about 5 cm in deep-sea sediment, although some burrows can infrequently extend deeper^{17,22,23}. Preliminary laboratory observations indicate that only a small decrease in water content is necessary to lock-in a post-depositional remanence in the sediment. This suggests that the difference in depth between acquisition of remanence and the sedimentation surface may not be excessive.

The applicability of such sediment reconstitution studies to palaeofield intensity measurements in deep-sea sediments is now being investigated.

This research was supported by the National Science Foundation. I thank Drs W. Lowrie and N. D. Opdyke for guidance and help.

Flocculation of Latices by Low Molecular Weight Polymers

POLYELECTROLYTES are increasingly being used as flocculants for electrostatically stabilised dispersions of colloidal particles in such diverse fields as water treatment and mineral processing¹. Suitable polyelectrolytes, which are usually effective at low concentrations (≤ 10 p.p.m.), invariably have a high molecular weight² (a viscosity average molecular weight $M_v > 10^5$). They seem to function by a bridging mechanism whereby the flocculant interferes with the free movement of the particles¹⁻⁶.

We now report that even low molecular weight non-ionic polymer molecules ($M_v \geq 10^3$ to 10^6) are able to flocculate some polymer latices. They also seem to function by a bridging mechanism but require the presence at the particle surfaces of suitable groups with which the flocculant can interact specifically.

The new phenomenon was first discovered with an apparently electrostatically stabilised aqueous polystyrene latex (mean radius 24 nm), prepared by the method of Ottewill and Shaw⁷. Figure 1a displays the course of flocculation, which was followed turbidimetrically, on addition of poly(ethylene oxide) (PEO) to the latex at 35°C. (The initial light scattering was compensated for.) Several samples of low molecular weight PEO (ex Union Carbide Australia Ltd) were examined using the latex at a particle concentration of $\sim 10^{12}$ cm⁻³. In the absence of PEO the particles exhibited long term stability, whether or not 0.2 M HCl was present (line 1). When low molecular weight PEO was added in the absence of 0.2 M HCl no flocculation could be detected at any polymer concentration. But the addition of PEO, at 20 p.p.m., of either $M_v = 4,000$ or 23,000 in the presence of 0.2 M HCl resulted in rapid flocculation of the latex (curves 2 and 3). The higher molecular weight polymer was the more effective. Very high molecular weight polymer $M_v = 1 \times 10^6$ was also an effective flocculant at concentrations of only a few p.p.m.

Polystyrene latices prepared by the method of Ottewill and Shaw⁷ possess surface carboxylic acid groups^{8,9}. To investigate the role of these groups, polystyrene latices were prepared at low temperatures ($< 30^\circ$ C); as we have shown elsewhere¹⁰, such latices possess no detectable surface carboxylic acid groups. Interestingly these latices failed to flocculate on addition of PEO in the presence of 0.2 M HCl. On the other hand, polystyrene latices sterically stabilised¹¹ by poly(acrylic acid) (PAA) of $M_v = 19,300$ were also found to be flocculated by low (and high) molecular weight PEO (Fig. 1b). Again 0.2 M HCl was necessary for flocculation. We note that in the absence of PEO these latices exhibit long term entropic stabilisation¹¹ (line 4).

The foregoing experiments point to the central role played

by the surface carboxylic acid group in promoting flocculation. They suggest the following mechanism for flocculation by low molecular weight polymers: At suitably low pH the surface carboxylic acid groups are predominantly unionised and so can H bond with the ether oxygens of the PEO chains. The occurrence of such H bonding is forcefully demonstrated by the phase separation of mixtures of PAA and PEO from aqueous solutions at low pH (refs 12 and 13). For the conditions relevant to curve 3 in Fig. 1a, the centres of the particles were separated, on average, by $\sim 1,000$ nm, if a cubic array is assumed. The r.m.s. end-to-end length of the PEO chains was calculated¹⁴ to be only ~ 10 nm. Obviously on average the polymer chains could not possibly span the distance between the particle surfaces. Therefore the PEO chains may reasonably be inferred to have become attached to one particle by H bonding to the surface carboxylic acid groups and to have become attached to a second (or more) particle(s) in subsequent Brownian collisions. Free movement of the latex particles was thus prevented, corresponding to bridging flocculation. According to this postulated mechanism, no flocculation would be expected at higher pH values because the ionised carboxylic acid groups would be unable to H bond with the PEO. Also no flocculation would be expected in the absence of surface carboxylic acid groups. Both expectations were realised.

Fig. 1 The % transmission as a function of time for polystyrene latices. *a*, Curves for latices containing surface carboxylic acid groups: 1, no PEO added; 2, PEO of $M_v = 4,000$ added; 3, PEO of $M_v = 23,000$ added. *b*, Curves for latices stabilised by PAA: 4, no PEO added; 5, PEO of $M_v = 4,000$ added; 6, PEO of $M_v = 23,000$ added. *c*, Curves for latices stabilised by PEO: 7, no PAA added; 8, PAA of $M_v = 19,300$ added. Flocculant added at 20 p.p.m. in *a* and *c* and 50 p.p.m. in *b*.

If this explanation is correct then it is also predicted that low molecular weight PAA should be able to flocculate latices stabilised solely by PEO chains. Figure 1c shows the flocculation induced by the addition of PAA ($M_v = 19,300$) to a polystyrene latex sterically stabilised in this case enthalpically by PEO ($M_v = 23,000$). Again no flocculation was evident unless 0.1 M HCl was also present to convert most of the carboxylic acid groups into the unionised form.

The phenomenon seems to be closely analogous to the bridging flocculation observed with high molecular weight polyelectrolytes. Both are characterised by the intervention of the polymeric flocculant by promoting 'sticky' collisions between the particles, the flocculated particles often being separated by some distance¹⁵. There is thus no need to reduce to near zero the repulsive potential energy between

the particles, whether electrostatically or sterically generated, to permit flocculation to occur.

We thank the Australian Research Grants Committee for financial support.

BIOLOGICAL SCIENCES

Genetic Differences in Conformational Changes of Albumin in the House Mouse

THE ability of mouse liver to convert mouse or bovine albumin to a faster migrating band under acid conditions of electrophoresis has recently been found to be controlled by a dominant gene, as observed in the SWR/J and several other strains of mice¹. Other strains, such as C3H/HeJ, had the recessive allele and were unable to convert albumin. The conditions used included a pH at which conformational changes in albumin are known to occur, suggesting that the strains of mice differ in a factor in the liver capable of converting albumin to a different conformational state. I report here evidence that the conversion of albumin can be reversed by lowering the pH markedly. This provides further evidence that a conformational change has taken place.

Livers from male C3H/HeJ and SWR/J mice were homogenized and centrifuged, and the supernatant was extracted using procedures described before¹. One volume of horse serum albumin (HSA, Fraction V, Sigma, 5 mg ml⁻¹ in 0.25 M sucrose) was added to 9 volumes of extract. An equal volume of solvent (citric acid, monohydrate: 15% sucrose, 1:5 (w/v), plus 6 M urea) was added to each extracted sample. Before electrophoresis 10 μ l was added to a slot, 5 volumes of an aliquot was diluted with 1 volume of concentrated HCl and 20 min later 12 μ l was added to another slot, and finally 10 μ l of an aliquot untreated with HCl was added to a third slot. Controls were also included in which 0.25 M sucrose replaced HSA or liver supernatant, but were otherwise handled as other

Fig. 1 Electrophoretograms showing the effect of liver extract and HCl on HSA. Channels 1-3 are (1) HSA+SWR/J liver extract+HCl; (2) HSA+SWR/J liver extract, and (3) HSA. Electrophoresis was as previously described¹. Gel buffer was 0.05 M Tris-citric acid, pH 2.4+3 M urea+10% 'Cyanogum'-41. Electrode buffer was 0.2 M glycine-citric acid, pH 3.5.

samples, although not treated with HCl. HSA was used because both slow and fast forms were electrophoretically distinct from proteins of mouse liver.

Results are shown in Fig. 1. HSA was present as a single, slower migrating band when not combined with liver (channel 3), whereas most was converted to a faster band when combined with liver extract of the SWR/J strain (channel 2). The latter result was not affected by the time when the sample was added to the slot, that is, before addition of HCl to an aliquot more than 20 min before electrophoresis compared with just before electrophoresis. Treatment with HCl (channel 1) lowered pH markedly (from 2.83 to 0.05) and converted much of the HSA to the slower migrating band. In C3H/HeJ mice (results not shown) HSA was not converted to a faster migrating band, but consisted only of a slow band migrating the same distance as in channel 3, with or without added HCl. Most of the mouse albumin of liver was also converted to a faster migrating band in the SWR/J but not the C3H/HeJ strain, as described previously¹; treatment with HCl converted a large portion to the slower migrating band in the SWR/J strain (Fig. 1), but there was no change in the C3H/HeJ strain.

My data show that liver of one strain of mouse but not of another can convert HSA to a faster migrating form. The genetic difference is clearly not in the primary structure of albumin, that is, amino acid sequence, since the same source of HSA was used in all preparations, but is rather a secondary alteration of the molecule. A conversion to a different conformational state is highly likely in view of the reversal from the faster to the slower migrating band after treatment with excess acid, especially since lowering the pH below 3.5 favours the expanded, slower migrating form². The reversibility of the change in albumin renders untenable the hypothesis that conversion of albumin from a slower to faster migrating form results from cleavage of a portion of the albumin molecule. These results point to the existence of two genes which control the structure of albumin, that is a conventional "structural gene" specifying primary structure³ and a second gene affecting secondary or tertiary structure.

Platelet Contractile Regulation in an Isometric System

We have previously shown that human platelets, in addition to actomyosin, the so-called thrombosthenin¹, contain a tropomyosin-like protein². Furthermore, we provided evidence for the presence in isolated platelet actomyosin of a control system which "turns-on" the Mg-ATPase of the contractile protein complex at a saturating level of 10^{-6} M Ca^{2+} (ref. 2).

Platelet contraction has usually been considered to be an irreversible process. Platelets have been found, however, to contain a membrane-associated relaxing factor, resembling the muscle sarcotubular system. This factor sequesters calcium from solution and behaves as a Ca^{2+} pump^{3,4}. It has been shown recently that in an isotonic contractile system, a platelet-containing clot relaxes in the presence of papaverine, theophylline or cytochalasin B (ref. 5). Here we used an isometric system to measure platelet contraction and relaxation and the calcium-sensitivity of these processes.

Cylindrical clots were obtained by pouring a human platelet-rich plasma suspension, immediately after thrombin addition, into siliconized glass tubes, 6×0.6 cm internal diameter, plugged at one end with parafilm. Saline was carefully layered over the suspension to abolish the meniscus. After 10 min the clot cylinder was poured into a Petri dish containing ice cold Tyrode solution to inhibit contraction. The clot was then tied at one end with a cotton thread to a rigid glass support and at the other end to a Grass force displacement transducer (FT 03 C) linked to a Grass Polygraph d.c. driver amplifier recording system. The clot was immersed in a bath of Tyrode solution containing 1.7 mM Ca^{2+} at 37°C and the tension was recorded.

The tension developed in the clot in this Ca^{2+} -containing isometric system increased with rising platelet concentration, similar to observations on clot retraction measured in a contractile isotonic system^{6,7}. The maximal tension was proportional to the initial cross-sectional area of the clot, and was independent of its length. Unlike in a muscle system, the cross-sectional area of the clot greatly decreased during isometric contraction, presumably as a result of transverse contraction associated with extrusion of serum from the fibrin-platelet network. In the Ca^{2+} -containing isometric system (experimental conditions described in the legend to Fig. 1), platelet-rich clots developed tension at an initial speed of $0.2 \text{ mg min}^{-1} \text{ cm}^{-2}$ (initial cross-sectional area) and reached a maximal tension of 1.8 mg cm^{-2} after 15 min. After maintaining a tension plateau for about 5 min, the clot relaxed spontaneously and irreversibly at a rate approximately half that of the development of the tension. This spontaneous irreversible

Fig. 1 Tension development in thrombin-clotted platelet-rich plasma in a Ca^{2+} -containing isometric system. Citrated platelet-rich plasma, 2 ml, containing $300,000 \text{ platelets mm}^{-3}$ and 250 mg% fibrinogen, were clotted with 0.5 NIH units thrombin (Parke-Davis). The clot was incubated at 37°C in Tyrode solution, containing 1.7 mM Ca^{2+} . The tension recorded is expressed in mg cm^{-2} (initial cross-sectional area).

Fig. 2 Effect of Ca^{2+} on the tension developed in a thrombin-clotted platelet-rich plasma. Except for Ca^{2+} concentration, the conditions were the same as in Fig. 1. The clot was washed and incubated in Tyrode solution containing variable Ca^{2+} concentrations in the pre-maximal contraction phase. Appropriate mixtures of 10 mM EGTA and 10 mM Ca-EGTA were used to obtain the desired Ca^{2+} concentrations, taking into account a dissociation constant of 1.9×10^{-7} for Ca-EGTA (ref. 29).

Fig. 3 Effect of Ca^{2+} on isotonic clot retraction and on Mg-ATPase activity of human platelet actomyosin. O, Citrated platelet-rich plasma was clotted with 0.5 NIH units ml^{-1} of thrombin in flamed test tubes in the presence of 10^{-8} M to 10^{-5} M Ca^{2+} adjusted with Ca-EGTA buffer as in Fig. 2. The percentage of clot retraction was calculated from the measured volume of expressed serum, 100% being defined as maximal clot retraction. ●, Mg-ATPase activity of human platelet actomyosin at varying Ca^{2+} concentrations was estimated as described elsewhere².

relaxation may be a sequel to platelet ATP depletion known to occur as a result of thrombin action^{8,9} and possibly to platelet membrane damage inherent in viscous metamorphosis¹⁰.

When a contracting clot, at pre-maximal tension, was treated with Ca^{2+} -free Tyrode solution containing 0.05 M ethylene glycol-bis-(2-aminoethyl ether) N,N'-tetraacetic acid (EGTA, a selective Ca^{2+} -chelator), relaxation immediately occurred (Fig. 2). When subsequently bathed again in Ca^{2+} -containing Tyrode, the clot contracted at the original initial speed. Addition of EGTA at the time when maximal tension was reached or later did not affect the speed of the spontaneous relaxation. When a contracting clot had developed half its maximal tension, it could be relaxed by lowering the free Ca^{2+} concentration (by the use of an EGTA-Ca buffer) to 10^{-8} M. The minimal concentration of Ca^{2+} required for maximal contraction was found to be 10^{-6} M, similar to muscle and platelet natural actomyosin systems². Cycles of contraction and relaxation could be induced several times in the same clot by varying the Ca^{2+} concentration (Fig. 2).

The effect of Ca^{2+} in a standard isotonic clot retraction system was studied for comparison. Retraction of a thrombin-treated platelet-rich plasma clot was half maximum at 3×10^{-7} M Ca^{2+} and reached maximum value above 10^{-6} M Ca^{2+} (Fig. 3). The latter Ca^{2+} concentration was identical

to both that required for maximal ATPase activity of thrombosthenin and that required for maximal tension of the platelet-rich plasma clot in the isometric system described here.

This study has shown that the clot contraction-relaxation cycle depends upon the presence of Ca^{2+} . Calcium, particularly intracellular platelet calcium, has long been suspected to be an essential requirement for clot contraction⁷. Indeed, platelets have been shown to contain high concentrations of Ca^{2+} which could be released by thrombin¹¹. The presumably intracellularly-bound Ca^{2+} would, in the process of release, be expected to interact with specific platelet actomyosin sites^{12,13}; subsequent interaction between actin and myosin would then occur and contraction would follow. In our study, thrombin-treated platelets showed permeability properties similar to glycerinated or skinned muscle fibres rather than intact muscle fibres, as they responded to externally added EGTA.

Two mechanisms may be suggested to account for the dependence of platelet contraction on the exterior concentration of EGTA-Ca^{2+} : the action of Ca^{2+} on thrombosthenin located on the outer surface of the platelet membrane, or the occurrence of a selective change in the platelet membrane permeability. In support of the first mechanism several authors have found thrombosthenin and thrombosthenin-specific ecto-ATPase on the external surface of the platelet membrane¹⁴⁻¹⁷, but these studies are considered inconclusive¹⁸. In support of the second mechanism it may be mentioned that thrombin is able to hydrolyse platelet membrane proteins¹⁹⁻²¹. Consequently, a change of platelet membrane protein conformation might occur and affect the local lipid structure, as has been discussed by Singer^{22,23} for hypothetical models. In addition, extracellular calcium can bind to phospholipid heads of synthetic lipid bilayers, neutralize their charges and produce a compression wave which is effective at long distances²³⁻²⁵. Such Ca^{2+} -generated compression waves might cause structural changes in proteins embedded in these lipid bilayers²³. This effect may explain the need for extracellular Ca^{2+} for platelet aggregation and contractile processes. Furthermore, thrombin has been shown to increase the rate of Ca^{2+} uptake by platelets¹¹.

The generation of tension in a contracting clot involves two processes, platelet contraction itself, and fibrin network collapse with extrusion of trapped serum. The mechanism by which platelets pull the fibrin fibres together is poorly understood. We venture to propose a model (I. C., and E. Katchalski, unpublished) taking into account the rigidity of the fibrin fibres which during clotting become intimately associated with the platelet membranes and converge towards the platelet

masses^{26,27}. Contraction of the platelet mass would reduce the angle between the attached fibrin fibres, their approximation amplifying with distance. Other platelet masses associated with these fibrin fibres would approach each other and tension would be generated in the clot (Fig. 4).

The clot contraction-relaxation cycles demonstrated in our experiments stress the physiological significance in platelets of both the sarcotubular system, functioning as a Ca^{2+} pump, and the contractile protein regulatory system. Our previous observations²⁸ support a regulation of the platelet contractile process of an actin-linked tropomyosin-troponin type rather than of a myosin-linked type.

Does Gonadotrophin-induced Ovulation in Mice cause Malformations in the Offspring?

GONADOTROPHIN treatment affects follicular maturation and induces ovulation in immature and mature mammalian females. This procedure has been used for experimental

research¹⁻⁸ as well as for clinical treatment in human anovulatory disease. Side effects reported when hormonally induced ovulation is followed by pregnancy include: frequent resorptions, spontaneous abortions with chromosomal anomalies, extrauterine and multiple pregnancies and difficulties in giving birth⁹⁻¹⁶.

This article demonstrates that after hormonally induced ovulation, malformations can occur in the embryos of mice. This is of interest, as Dyson and Kohler reported two clinical cases of anencephaly following gonadotrophin-induced ovulation¹⁷.

Ninety randomly bred virgin mice (Swiss albino), 6 to 9 weeks old, were caused to ovulate by intraperitoneal injections of 5 IU pregnant mare's serum gonadotrophin (PMS, 'Gestyl', Organon, Holland) in 0.15 ml of 0.9% saline and of 5 IU human chorionic gonadotrophin (HCG, 'Pregnyl', Organon, Holland) in 0.1 ml of 0.9% saline 48 h later. After the second injection the females were caged overnight with males (same strain and of proven fertility). Insemination was verified the following morning by the presence of a copulatory plug.

Table 1 Observations on Pregnant Females Following Gonadotrophin Treatment and Normal Mating

	Number	Injected (%)
Treated	90	
Mated	36	38.9
Pregnant	32	34.4
		Pregnant (%)
Deaths*	2	6.5
Normal delivery†	2	6.5
Complicated delivery‡	2	6.5
Blocked delivery§	26	80.6

* Death after hormone treatment occurred on the 18th d of gestation. These females had three and twelve normal foetuses respectively.

† One female gave birth to thirteen normal embryos, the other delivered three living and eight dead embryos.

‡ Females which had difficulties during delivery started to give birth to both dead and living embryos. They also failed to give complete birth, feeding on the embryos delivered first. They were autopsied 6 h after they had started to deliver; the normal length of the delivery procedure does not exceed 2 h. Living foetuses were still found in the uterus.

§ Untreated control females delivered between the 19th and 20th d of gestation, so animals which had shown blood-stained vaginal smears for 2 d were killed between the 19th and 21st d, the uteri were opened and respiration was induced manually in the individual embryos. Those which survived more than 1 h were placed with foster mothers, which had delivered on the same day and had been deprived of their litters.

Table 2 Reproductive Performance of Gonadotrophin-treated Females

	Treated	Control
Litters	32	8
Litters with anomalies	5	0 0.05 > P > 0.01
Average litter size	14.3 ± 6.5	12.4 ± 2.7*
No. of nidations	665	112
Living offspring	48.5%	93.8%
Dead foetuses	20.3%	1.8%
Anomalous (total offspring)	1.8%	0 0.01 > P > 0.001
Resorbed in utero	31.2%†	4.5%
No. of sexed embryos	336	521‡
Males	35.5%	51%
		P < 0.001
Females	64.6%	49%
Embryos placed to foster mothers	184	84
Viability up to 1 h	76%	99%
Survival to 23 d	66%	85%

* In addition to the controls (Caesarean sectioned), twenty-four normally delivering females of the same strain were used to estimate average litter size.

† Partly with malformations.

‡ For the estimation of the sex ratio in controls, an additional thirty-six normally delivering females of the same strain were used.

Fig. 1 Malformations of the forepaw (aplasia of the 5th digit, thumb arrowed). *a*, Left forepaw of newborn mice; *b*, right forepaw of mice 23 d post partum (the offspring of the treated female died at this age).

This day was designated as day 1 of pregnancy. No further treatment was given.

The results obtained with gonadotrophin-treated and normally mated mice are given in Table 1. Details of pregnancies at the time of autopsy of females subjected to gonadotrophin treatment are given in Table 2. The litters of females injected with hormones ranged in size from two to twenty-six, control litter size was between nine and sixteen. Although 99% of a total of eighty-four control embryos could be placed to foster mothers, only 76% of the embryos (total 184) obtained from treated females survived the first hour. Most of the embryos of injected females died within the first 5 d and those which lived to 23 d post partum survived thereafter. Death of controls occurred only during the first 3 d. This corresponds with the usual death rate of normally bred animals.

The viability of embryos of treated females of approximately the same litter size as of controls (up to sixteen embryos) is 64.4% (compared with 85% of controls), whereas the rate of survival in embryos of all treated females (including high litters also) is 66%. This indicates that embryonic death is not a result solely of excessive litter size in treated females.

Embryos of females injected with hormone, as well as of controls, were sexed after artificial and normal birth respectively. The sex ratio of males to females is 1 : 1.82 in the treated animals, whereas the controls show the usual slight imbalance in favour of males (ratio 1 : 0.96). This suggests that gonadotrophin treatment before pregnancy directly influences the distribution between the sexes.

The observed malformations are illustrated in Figs 1 and 2. Embryos of females (hormone-injected) with a litter size between fifteen and twenty-two showed postaxial oligodactylism of the forelimb. One embryo had a forelimb dysmelia of the reduction type which was also seen on late resorptions. Seven

Fig. 2 Malformation of the right forepaw (dysmelia) and cystic bladder (1). This animal was dead at the time of Caesarean section. Note the absence of digits 2, 3, 4 and 5. The thumb (arrow) is suppressed to a thin structure.

of eight embryos were found to be abnormal with respect to the right forelimb (six females, one male), whereas the eighth (male) showed an aplasia of the left forelimb. The abnormalities observed in these experiments have a striking similarity to less severe lesions obtained in rats treated with acetazolamide during mid-pregnancy^{18,19} and in mice treated with 5-fluoro-2-deoxycytidine²⁰. The malformations reported here are phenocopies of the oligodactylism described by Grüneberg²¹ where, as a rule, the postaxial areas of the limb skeleton are also affected. The only difference is that in oligodactylism the left forelimbs are slightly more often affected, whereas in the observations reported here, as after treatment with acetazolamide, more right forelimbs were affected.

This study has shown that gonadotrophin treatment before pregnancy can result in statistically significant anomalies and a shifted sex ratio, as well as in a reduced survival chance after Caesarean section.

Identification of Skin in Airborne Particulate Matter

In the assessment of airborne particulate contamination, it is necessary to identify and quantify the particle species in the environment. Many of the particles recovered from the air have been identified microscopically as being skin scales shed from humans, similar to those shown in Fig. 1. In some circumstances particles may be recovered which are fragmented and appear "dirty" and their microscopic identification then becomes difficult¹. This is especially true when airborne samples from outside air contain small fragments of leaves or the wax cuticle from plant surfaces which are similar in appearance to skin scales.

Here we describe a technique for identifying skin particles by analysis of the surface fats on the recovered particles. In this way many of the airborne particles which have been dismissed as "dust of unknown origin" are shown to have originated from the skin of humans or animals.

The composition of the cuticle and surface waxes on leaves is well documented². In most species, the hydrocarbons in the surface wax are saturated and consist predominantly of substances with an odd number of carbon atoms. In cabbage leaves, for instance, the surface wax consists of a complex mixture of long chain compounds, but some 65% of this wax is made up of only seven different straight chain compounds, all twenty-nine carbon atoms long. One compound, normal-nonacosane (n-C₂₉), makes up more than 90% of the hydrocarbon fraction. Table 1 shows the average composition of human skin surface fat taken from the forearm³.

Our skin identification technique is based on the presence of squalene in human skin and its absence from the surface layer of leaves. (As a preliminary to the analysis of samples of airborne particles, the presence of squalene on the skin surface was confirmed by the use of a Varian Aerograph 2700 gas chromatograph coupled to a Varian MAT 731 mass spectrometer and data were processed by the Varian 100 MS Spectro System.) Skin was gently scraped with a scalpel blade and the dislodged skin scales were collected. The fats were then dissolved in a known quantity of carbon disulphide and an aliquot injected into a Perkin Elmer chromatograph. The squalene content was shown to be of the order of 1% by weight of the collected skin scales (Fig. 2) and the quantities of squalene recovered by petroleum ether washing of the skin of various subjects were

Fig. 1 Scanning electron micrograph of skin fragments some 2 to 5 µm across and 0.5 µm thick, recovered from room air.

Table 1 Composition of Average Skin Surface Fat from the Forearms of Men^a

Free fatty acids	30.0%
Triglycerides	32.5%
Straight chain wax esters	10.7%
Branch chain wax esters	
Cholesterylestes	4.3%
Cholesterol (free)	2.5%
Squalene	5%
Paraffins	7.5%
Unidentified unsaponified fat	7.5%

Table 2 The Percentage of Skin (by Weight) in the Collected Air Samples from Four Locations

Origin of samples	Particle size ranges		
	6 to 2 μm	2 to 0.7 μm	0.7 to 0.4 μm
<i>a</i> Garden	0.4	0.6	0.8
House	0.4	0.7	0.8
Laboratory corridor	1.0	0.5	0.5
<i>b</i> Underground system	5.5 to 3.5 μm	3.5 to 2 μm	2 to 0.3 μm
	10	10	10

Airborne particles were recovered from the air of various environments using either, *a*, a Casella Cascade Impactor or, *b*, an Andersen Mini-Sampler. The collection disks in these samplers were thoroughly cleaned with redistilled carbon disulphide before the sample was obtained. The particulate matter was removed from the disks by scraping with a thoroughly clean scalpel and then transferred to a small glass tube. The disks were weighed before and after the particles were removed and 5 μl of re-distilled carbon disulphide was added to the sample of particles from a microsyringe. The solvent and particles were drawn in and out of the syringe needle several times to ensure mixing before being injected into the gas chromatograph.

consistently of the order of 1 $\mu\text{g cm}^{-2}$ of skin area washed.

Samples of airborne particulates were collected from the open air of a rural area, indoors in the same rural area, from the corridors of the NIMR Laboratories in Hampstead and from the microenvironment of a passenger travelling in the London Underground system. The collected particles deposited on sampling disks in each of the sampling apparatus so that the fraction on any disk was within a well defined particle size range. Very little material was collected by the samplers for particles

Fig. 2 Chromatogram of the fats on skin scales scraped from the body surface. The gas chromatograph used was a Perkin Elmer F-11 single column instrument with a flame ionization detector and the column was 6 foot $\times$ 3 mm internal diameter glass containing OV-1 3% on Gas Chrom Q. All injections were made directly on to the column packing. The oven temperature was 260°C isothermal and the injection port temperature 260°C. The carrier was nitrogen at 10 pounds per square inch inlet pressure. The air pressure was 25 pounds per square inch and the hydrogen pressure was 18 pounds per square inch. The solvent used was re-distilled carbon disulphide. Its purity was checked by a 4 μl injection before each set of samples was run on the chromatograph. Great care was necessary to avoid contamination at all stages of sample handling. (Simply touching the outside of the syringe needle with the fingers would give measurable amounts of squalene on the chromatogram.) All glassware was cleaned in Decon 90, rinsed thoroughly with water, dried and then rinsed with re-distilled carbon disulphide. Random checks were made to ensure the cleanliness of the glassware. *a*, Cholesterol; *b*, squalene.

Fig. 3 Chromatograms showing the presence of squalene (arrowed) in air samples from, *a*, garden air; *b*, house air; *c*, laboratory air; *d*, air from the London Underground system.

in the largest size fraction (that is particles greater than 20 μm diameter) and these deposits were not analysed. Figure 3 shows the chromatograms produced from the airborne particulates from the four sampling locations. The percentage of skin (by weight) detected by the chromatograph (given that the squalene weight content of skin is 1%) for these locations is summarized in Table 2.

The percentage of the total collected particle weight, identified as skin by the presence of squalene, in the garden and house air was similar throughout the size range 0.4 to 6 μm , but some five times more air had to be sampled in the garden than in the house to give an adequate sample for analysis.

The total weights of skin found in the two locations are in reasonable accord with other results, to be reported elsewhere, which show that the number concentrations per unit volume of air (in the size range 0.5 to 10 μm) are consistently an order of magnitude greater in the house air than in the garden air when the size spectra of all species of airborne particles are considered.

The gas chromatograph makes possible the detection and quantification of squalene in particles recovered from the air and from the surface fats of the human skin. As this compound is absent from the surface waxes of plant leaves, the technique described here may be used in the assessment of environmental contamination caused by desquamated skin scales.

We thank Dr A. M. Lawson of the Division of Clinical Chemistry at the Clinical Research Centre, Harrow, for the mass spectroscopy. We also thank Dr E. A. Johnson of the National Institute for Biological Standards and Control, Hampstead, for suggestions.

Carbon Isotope Discrimination in Photosynthesis of CAM Plants

SUCCULENT plants capable of Crassulacean acid metabolism (CAM) show extremely variable carbon isotope discrimination ratios^{1,2}. This ratio, usually expressed as a $\delta^{13}\text{C}$ value referred to a standard³, has emerged as a useful diagnostic criterion to determine photosynthetic pathways in higher plants⁴⁻⁶. Species with the C_4 photosynthetic pathway⁶ show less negative $\delta^{13}\text{C}$ values than do species with the C_3 photosynthetic pathway. The difference in isotope discrimination is believed to be a result of the different fractionation characteristics of the primary phosphoenolpyruvate (PEP) carboxylase of C_4 plants and primary ribulosediphosphate (RuDP) carboxylase of C_3 plants⁷. Within a species, the $\delta^{13}\text{C}$ value for total carbon does not usually vary by more than $\pm 0.5\text{‰}$, and it is largely insensitive to environmental conditions during growth⁸, although the soluble components within a particular leaf may show some variation⁹. Examples of the constancy of $\delta^{13}\text{C}$ values are shown in the genus *Atriplex*, where C_4 species have less negative values (for total carbon) of -8 to -12‰ than C_3 species which range between -25 and -27‰ (ref. 8).

Here we show that the $\delta^{13}\text{C}$ value for total carbon in CAM plants undergoes significant and predictable responses to controlled growth conditions. The $\delta^{13}\text{C}$ value is correlated with other physiological events to demonstrate that the growth conditions determine the expression of C_3 -like or C_4 -like components of photosynthetic metabolism in CAM plants.

CAM plants such as *Kalanchoe daigremontiana* may fix CO_2 in the light or in the dark. Plants subjected to short hot days and long cool nights rely almost entirely on dark CO_2 fixation for net carbon gain^{10,11}. Carbon dioxide fixation in the dark in CAM plants involves a primary carboxylation of PEP to form oxaloacetate, which is reduced to malate¹². Subsequent metabolism of malic acid to carbohydrate in the light completes the analogy between these temporally separated events and the same spatially separated steps of C_4 photosynthesis^{6,13,14}.

The same CAM species may be grown in conditions of long cool days and short warm nights, in which case CO_2 fixation is largely restricted to the light period^{10,11}. During steady state photosynthesis, *K. daigremontiana* shows a light saturated CO_2 compensation point of about 50 p.p.m. in air (W. G. A., B. O. Austin, and R. O. Slatyer, in preparation). Although malate and aspartate contain a variable proportion of total radioactivity¹⁵ during short term photosynthesis in $^{14}\text{CO}_2$ pulse-chase studies show that the C_4 acids continue to accumulate label in the light (Fig. 1). The C_4 acids are end products of $^{14}\text{CO}_2$ fixation in the light¹⁵, and are not transitory intermediates as is the case with the C_4 pathway of photosynthesis. The CO_2 compensation point, and the pulse-chase behaviour of 3-phosphoglycerate and sugar phosphates (Fig. 1), suggest that CO_2 fixation in the light in *K. daigremontiana* involves direct carboxylation of RuDP and the C_3 pathway of photosynthesis.

Succulents may change their photosynthetic pathway in response to environmental influences other than temperature. Winter and von Willert¹⁶ discovered that the C_3 plant *Mesembryanthemum crystallinum* may be induced to fix CO_2 in the dark when treated with NaCl. The dark fixation of CO_2 results in a diurnal accumulation of malic acid similar to that found in CAM plants grown under short hot days and long cool nights.

We have used these two techniques, the regulation of day/night length and temperature during growth of *K. daigremontiana* and *K. blossfeldiana*, and the salinization of *M. crystallinum*, to investigate the effects of controlled environment during growth on CO_2 fixation, malate synthesis, and $\delta^{13}\text{C}$ values in CAM plants. Plants were grown in the specified conditions in CSIRO phytotron cabinets or artificially illuminated growth chambers. *M. crystallinum* was grown in soil in a greenhouse for 7 weeks before irrigating some plants with 0.35 N NaCl. Salinized and control plants were assayed 3 weeks later. Carbon dioxide fixation was followed by infrared gas analysis and diurnal changes in acid were estimated by

Fig. 1 Percentage distribution of ^{14}C in photosynthetic products extracted from leaves of *K. daigremontiana* exposed to $^{14}\text{CO}_2$ in a 15 s pulse, followed by a chase in $^{12}\text{CO}_2$ for up to 600 s. Leaf material was removed from plants in the 27/15°C regime of experiment 2 (Table 1) at the end of the light period. Leaf segments (2.5×4 cm) were illuminated for 10 min with $30,000 \text{ erg cm}^{-2} \text{ s}^{-1}$ of white light at 28°C before exposure to $50 \mu\text{Ci } ^{14}\text{CO}_2$ ($60 \mu\text{Ci } \mu\text{mol}^{-1}$) in a 75 ml vessel. (●), Malate + aspartate; (○), sugars; (■), sugar monophosphates + 3-PGA; (□), sugar diphosphates.

titration and direct assay for malate. The $\delta^{13}\text{C}$ value was determined by mass spectrometry after combustion of dried plant material¹⁷. Five to twenty plants were sampled in each treatment.

Table 1 shows the results of four such experiments. Treatments which permit CO_2 fixation predominantly in the light period (C_3 -like photosynthetic mode) result in small changes in malic acid content and yield more negative $\delta^{13}\text{C}$ values. Treatments which restrict CO_2 fixation predominantly to the dark period (C_4 -like photosynthetic mode) result in large changes in malic acid content and less negative $\delta^{13}\text{C}$ values. It is unlikely that the increased malic acid content is in itself responsible for the more negative $\delta^{13}\text{C}$ values, which presumably apply to all components of the tissue⁹. Duplicate determinations of the $\delta^{13}\text{C}$ value in experiments 2 and 3 show the reliability of the method when based on a large number of plant samples.

There is a good correlation between the principal mode of CO_2 fixation during growth and the $\delta^{13}\text{C}$ values. Growth dependent on dark fixation results in less negative $\delta^{13}\text{C}$ values than growth which is largely dependent on CO_2 fixation in the light. The magnitude of the change in $\delta^{13}\text{C}$ value, and absolute $\delta^{13}\text{C}$ values, display some variation between experiments and species which may be explained in terms of the conditions of the experiments. In experiment 1, for example, growth of *K. daigremontiana* on the 20/25°C regime was five-fold greater than that on the 30/15°C regime. In experiment 4, *M. crystallinum* was grown for 7 weeks in control conditions before treatment with 0.35 N NaCl. The proportion of tissue carbon laid down in the C_4 -like growth conditions of both of these experiments is smaller than that laid down in the C_3 -like conditions. The changes in $\delta^{13}\text{C}$ values in the C_4 -like treatments are thus considerably underestimated.

We conclude that CAM plants have the option of a C_3 -like or a C_4 -like mode of photosynthetic metabolism. In most conditions it is likely that a CAM plant will receive contributions from both components during its development. The proportion gained in the light or dark responds rapidly to changes in temperature on a day to day basis, as shown by Neales¹¹. The final $\delta^{13}\text{C}$ value shown by the tissue should reflect the proportion of carbon gained through each pathway during growth.

Table 1 Effects of Controlled Growth Conditions on the Photosynthetic Behaviour of Succulent Plants Capable of Crassulacean Acid Metabolism

Species and tissue	Growth period (weeks)	Temperature day/night (°C)	Day length (h)	Illumination	Photosynthetic mode	Diurnal malate change ($\mu\text{mol g}^{-1}$ fresh wt)	$\delta^{13}\text{C}$ value (‰)

* Approximately 6×10^6 erg $\text{cm}^{-2} \text{s}^{-1}$ (400–700 nm) with day length extended with low intensity tungsten lamps.

† Approximately 3×10^4 erg $\text{cm}^{-2} \text{s}^{-1}$ (400–700 nm) from tungsten lamps and fluorescent tubes.

‡ Not measured here, see ref. 10.

Our experiments show that a variety of environmental conditions may regulate the proportion of carbon gained by either pathway. It is likely that the availability of water may be of paramount importance. Kluge and Fischer¹⁸ showed that droughting *Bryophyllum tubiflorum* rapidly reduced its ability to fix CO₂ in the light (the C₃-like component). Consistent with these observations, we have found that droughting mature *K. daigremontiana*, grown on the 20/25° C treatment of experiment one, made the $\delta^{13}\text{C}$ value less negative. After 9 weeks of drought, the control $\delta^{13}\text{C}$ value of -22.8 ± 0.8 ‰ moved to -16.2 ± 0.3 ‰ as the plants relied increasingly on the dark CO₂ fixation; the C₄-like component of photosynthesis. Similar data have been obtained for the $\delta^{13}\text{C}$ values of *Optunia inermis* throughout its range in eastern Australia; in arid regions of central southern Queensland, $\delta^{13}\text{C}$ values for this species range between -11 and -13 ‰ and in the more temperate, higher rainfall areas of coastal southern New South Wales we have found values of -16 to -18 ‰. Environmental control of the photosynthetic options of these plants has brought about predictable changes in the $\delta^{13}\text{C}$ value.

Our collaboration was assisted by a CSIRO grant to O. Q. We are grateful for the controlled environment facilities provided by the CSIRO Phytotron, Canberra, and to Mrs K. A. Card for conducting the $\delta^{13}\text{C}$ analysis.

Accelerated Germination by Osmotic Seed Treatment

CROP seeds sown in cold soil are notoriously slow to emerge and it would obviously be desirable to shorten the time from sowing to seedling emergence and the time between the emergence of the first and the last seedling. This has occasionally been achieved by the pre-sowing seed treatment sometimes referred to as 'hardening'¹⁻³ or 'advancing'⁴ involving repeated cycles of imbibition of a carefully controlled quantity of water, followed by drying back the seeds before the radicles emerge but results have not been consistent. There have been some successful attempts to replace this method by imbibition of seeds in salt solutions⁵⁻⁷; tomato seeds thus treated for 6 d exhibit a much higher level of RNA production during germination than untreated seeds⁸.

Fig. 1 Germination rate of onion seeds in response to osmotic pretreatment. Effect of water potential, temperature and duration of treatment. Seeds were placed on filter papers moistened with solutions of a polyethylene glycol of high molecular weight, Carbowax 6000 (Union Carbide) of -10 , -12.5 or -15 bar osmotic potential⁹ and at temperatures of 10 , 15 and 20°C in the dark (batches of fifty seeds on four Whatman No. 1 filter papers in 8 ml of solution per 9 cm diameter Petri dish). After 3, 7, 11, 15, 19 and 23 d, four replicates of each of the treatments were thoroughly washed and surface dried. The seeds were then placed in other Petri dishes similarly prepared but with distilled water and were allowed to germinate at 10°C in the dark. . . . , -10.0 bar osmotic potential; - - - , -12.5 bar osmotic potential; - · - · - , -15.0 bar osmotic potential; —, untreated. *a*, 20°C ; *b*, 15°C ; *c*, 10°C .

By using a polyethylene glycol of high molecular weight, we have avoided the complications of both 'hardening' and the use of salts. Promising results have been obtained in preliminary experiments on carrot (*Daucus carota* L.) and red beet (*Beta vulgaris* L.), but we report here only on onion (*Allium cepa* L.) seeds.

All osmotic pretreatments resulted in an increase in the rate of radicle emergence (Fig. 1) depending in magnitude on

all three components of the preparatory treatment, that is, osmotic potential, temperature and duration. There was no effect on the percentage of seeds germinated but certain treatment combinations permitted germination of some seeds in the osmotic solution (Table 1).

For every temperature and osmotic potential combination, increasing treatment duration initially increased the rate of subsequent germination. At 15°C and 20°C , however, an optimal duration was found beyond which there was no further benefit and in some cases an eventual decline. Almost all comparable rates of germination were lower after treatment at 20°C than 15°C . At 10°C the optimal duration may not have been reached in this experiment.

When seeds were treated at 10°C and 15°C , a lower osmotic potential resulted in a lower rate of germination and a longer treatment was needed for the seeds to reach any desired rate of germination. Treatment at the lowest temperature caused a slower increase in the rate of germination than treatment at the higher temperatures, but ultimately resulted in the highest rate achieved. The combination of -10 bar and 15°C for 11 d, however, was nearly as successful in increasing the rate of germination of the seed population as the best treatment; -10 bar at 10°C was 0.8 d, when the resulting median time from sowing to radicle emergence at a germination temperature of 10°C was 0.8 d, which compared with 9.3 d for untreated seeds (Fig. 2). It would be hard to better this result.

This technique has fascinating physiological implications,

Fig. 2 Germination of onion seeds in response to 23 d osmotic pretreatment in PEG (Carbowax 6000) solution of -10 bar potential at 10°C . Germination at 10°C on filter paper moistened with water. The pretreatment increases both the rate and the uniformity of germination. —, Pretreated, washed and dried; - - -, untreated.

In vitro Control of *de novo* Flower, Bud, Root, and Callus Differentiation from Excised Epidermal Tissues

AMONG the plant species capable of neoformation, a much larger number are capable of root and vegetative bud formation than of direct flower neoformation. For most materials, the formation of buds or roots or flowers concerns different tissues, such as epidermis, perivascular or callus tissue of cambial origin, and each tissue maintains complex correlation with the surrounding tissues.

The study of the control of organogenetic differentiation is faced with certain difficulties because of the different tissues involved in the origin of different types of organogenesis and the complexity of the material: lack of criteria for a valid study of changes during organogenesis and for rigorous comparisons among the different types of organogenesis.

This problem was simplified when it was found that a few superficial cell layers excised and cultured *in vitro* have organogenetic potentialities which can be controlled at will. From very small explants of *Nautilocalyx lynchei* (5 mm × 2 mm), composed of one to five layers of foliar epidermal and subepidermal cells, mitoses without organogenesis (non-organogenetic differentiation), mitoses leading to the controlled formation of roots (Fig. 1) or vegetative buds (Fig. 2) (organogenetic differentiation) were induced from the same cellular layer, the epidermis, each cell of which divides¹. Thus, by the *in vitro* culture of a few superficial cell layers, it is possible to show experimentally the capacity for callus formation and *de novo* formation of roots up to then apparently inhibited. In leaf or stem fragments, root formation is confined to perivascular tissue.

With such materials, certain fundamental problems in organogenesis, which are difficult to study using relatively large organ fragments, can be examined. For example, for *Nautilocalyx*, where bud and root neoformations arise from epidermal cells, it would be possible to study the evolution and distribution of organogenetic centres by observing the thousands of cells on the epidermal surface to determine whether there is a special mode of distribution of these centres in relation to the presence of basal hair cells or stomata.

To the potentialities for bud, root and callus formation, we were able to add the direct *de novo* formation of floral buds on the explant without intermediate callus or leaf

Fig. 1 a, Longitudinal section of an explant of *Nautilocalyx* showing the epidermal origin of the root primordia organized *de novo* from divided epidermal cells. (×160.) b, *De novo* formation of roots from epidermal tissue explants after 37 d. e, Epidermis.

formation by applying the techniques described for *Nautilocalyx* to explants composed of three to five layers of epidermal and subepidermal cells excised from floral ramifications of *Nicotiana tabacum* "W.38". These explants are excised with a scalpel from floral ramifications previously disinfected in a 7% hypochlorite solution for 10 min, and planted on an aseptic culture medium composed of mineral elements, vitamins, auxin, cytokinin and sucrose.

Depending on the relative concentrations of the auxin, cytokinin and sucrose and on certain environmental factors, such as light and temperature, different types of differentiation can be induced in 10 to 14 d: callus formation which has been maintained without organogenesis for 2 yr, root formation, vegetative shoot formation and floral bud formation (Fig. 3). This last type of organogenetic differentiation is the most interesting. It implies that stimulation of mitoses takes place in cells which had lost

Fig. 2 Explant showing the *de novo* shoot formation, the surface covered with buds after 37 d. (×8.)

Fig. 3 Surface of the explant covered with floral buds formed *de novo* (arrows). 20 d stage. ($\times 2.5$.)

their capacity to divide, and that, after a short phase of production of floral parts, meiosis occurs.

Up to a certain stage, each one of these types of organogenesis can be converted into a different one. After this point, differentiation is irreversible.

An analysis at the cellular level has established that all these types of differentiation originate from the same cellular layer, the subepidermal layer, each cell of which participates in the differentiation. It is thus relatively easy to study the cellular and molecular modifications which occur in this layer during each type of organogenetic differentiation or at the exact moment of conversion from one programme to another.

These new experimental systems, with others developed in our research group, will facilitate a more precise approach to the determinism of differentiation in pluricellular systems by their simplicity and homogeneity.

Locomotor Affinities of *Hominoid* Tali from Kenya

A CONTRIBUTION to this journal¹ is among several that have attracted criticism from Oxnard². This communication has two objects; first, to reply to comments by Oxnard which relate to a possible ambiguity in the earlier communication; second, to present the results of a new analysis which provide additional evidence for the interpretation of the mode of locomotion of East African dryopithecines.

The object of the earlier work was to test the hypothesis, formulated by the late L. S. B. Leakey³, that two tali, one found at Songhor (CMH 145) and the other at Rusinga (CMH 147), may belong to the taxon "*Kenyapithecus africanus*", a putative early hominid. A multivariate canonical analysis, using extant hominid and pongid comparative material⁴, was performed. The first canonical axis produced clustering of the groups which

Fig. 1 Plot of canonical axes I and II. Circles are drawn with a radius of two eigenvalues. 1, *Gorilla*; 2, *Pan*; 3, *Papio*; 4, *Cercopithecus* (*mona* and *nictitans*); 5, *Colobus*; 6, *Pongo*.

corresponded to accepted locomotor classifications based on anatomical and behavioural analyses. This demonstrated the efficacy of the canonical coefficients of the first axis as locomotor discriminators. By contrast, the second and higher canonical axes failed to distinguish between "knuckle-walking" apes and bipeds. Thus, *a posteriori*, the canonical coefficients of the second and higher axes had no individual usefulness as discriminants between the extant locomotor groups.

The canonical coefficients for the first canonical axis were then used to process the data for the two fossil tali and an additional talus from Rusinga (234'50), and it was found that these tali lay closer to the knuckle-walking locomotor category than to the bipeds. This was taken as evidence that complemented and substantiated earlier morphological assessments that these tali are pongid or dryopithecine and not hominid.

Oxnard has suggested that the D^2 values indicate the affinity of the fossil tali for the knuckle-walking locomotor group confined to the first canonical axis, and is dependent on the limited choice of comparative groups. He continues, "the *Proconsul* tali are completely unlike African apes rather than similar as previously assessed", presumably because the sum total of the individually insignificant deviations in the second and higher axes place the fossils several units of Generalized Distance away from the extant apes.

Therefore, in order to investigate further the functional relationships of these fossil tali, and to attempt to reconcile these seemingly opposed views, a new canonical analysis has been performed.

The new comparative groups, with their locomotor classifications, are listed in Table 1. An attempt has been made, within the limits of available material, to improve the resolution of this technique by including a wider variety of sub-human Old World primate locomotor modes. Mahalanobis D^2 distances and canonical variates were calculated from measurements on the tali as outlined previously⁴. Seven significant canonical axes, of which the first three contained 97% of the total variability, were produced; subsequent axes did not individually contribute significantly to the discrimination.

Table 1 Comparative Groups

Groups	1 <i>Gorilla</i>	2 <i>Pan</i>	3 <i>Papio</i>	4 <i>Cercopithecus</i> <i>mona/nictitans</i>	5 <i>Colobus</i>	6 <i>Pongo</i>
No. of specimens	50	50	42	17	16	15
Locomotor classification	Knuckle walker	Knuckle walker	Quadruped	Quadruped	Quadruped (with leaping)	Brachiator (hind limb grasping)

Table 2 D^2 Distances and Probability Levels between Group Means

Groups	1	2	3	4	5
2	3.4 ($<0.1\%$)				
3	18.8 ($<0.1\%$)	14.9 ($<0.1\%$)			
4	18.2 ($<0.1\%$)	14.2 ($<0.1\%$)	1.6 (1.0%)		
5	47.4 ($<0.1\%$)	32.7 ($<0.1\%$)	25.4 ($<0.1\%$)	20.5 ($<0.1\%$)	
6	47.1 ($<0.1\%$)	34.5 ($<0.1\%$)	26.9 ($<0.1\%$)	21.2 ($<0.1\%$)	34.3 ($<0.1\%$)

eschew the former two groups and cluster with the combined knuckle-walking and quadrupedal groups. In axis I particularly, CMH 145 behaves differently from the other two fossil tali.

The Mahalanobis D^2 distances between the group means, with their probability levels, are given in Table 2; the D^2 distances of the fossil tali from the extant group means, along with probability levels, are given in Table 3. These distances confirm the dissimilarity between the fossil tali and those of both *Pongo* and *Colobus*. One talus, CMH 145, has no close affinity with any of the extant locomotor groups. The other two tali are closely related to tali of the quadrupedal group (*Papio* and *Cercopithecus*) and one, CMH 147, shows some affinity with the knuckle-walking tali.

Table 3 D^2 Distances and Probability Levels between Groups and Special Cases

	Comparative groups					
	1	2	3	4	5	6
	<i>Gorilla</i>	<i>Pan</i>	<i>Papio</i>	<i>Cercopithecus</i>	<i>Colobus</i>	<i>Pongo</i>
Fossil tali						
CMH 145	13.7 (5.0%)	18.4 (1.0%)	13.5 (5.0%)	14.8 (5.0%)	64.2 ($<0.5\%$)	50.5 ($<0.5\%$)
CMH 147	12.2 (10.0%)	8.7 (25.0%)	3.5 (85.0%)	5.7 (50.0%)	26.5 ($<0.5\%$)	30.6 ($<0.5\%$)
234'50	21.3 ($<0.5\%$)	17.7 (1.0%)	0.5 (99.0%)	2.5 (90.0%)	29.6 ($<0.5\%$)	29.7 ($<0.5\%$)

A plot of canonical axes I and II (Fig. 1) shows a clear separation of the knuckle-walking and quadrupedal locomotor groups, with no such separation between *Pongo* and *Colobus*. A further plot of axes II and III (Fig. 2) shows that axis III is a strong discriminator between *Pongo* and *Colobus* but has little effect on the other groups. Thus, between them these three axes produce a three-dimensional separation of extant samples that is consistent with current locomotor classifications; tali coming from primates with different locomotor modes are rarely confused in this analysis.

Subject to certain limitations, as outlined by Gower⁵, the canonical coefficients derived from the analysis can be used to determine the position of samples of extinct fossil primate genera in the same multivariate space.

The positions of the fossil tali have been plotted for the first three axes. In axis I (which effectively discriminates between a knuckle-walking and quadrupedal gait) two of the fossil tali are clustered with the quadrupeds. The third talus, CMH 145, is not associated with any extant locomotor group. In axis III, which successfully separates *Pongo* and *Colobus* from each other, from the quadrupeds and from the knuckle walkers, all three fossils

Thus, by focusing attention on how the talus varies between locomotor modes in a more extensive series of sub-human primate genera than were used in the earlier analysis, two of the fossil tali appear to show the same morphological features as cercopithecoïd quadrupeds. These quadrupeds are characterized by a relatively long anterior tarsal segment, associated with the use of the metatarsal heads as the fulcrum for their propulsive movement. Their body weight is transmitted almost exclusively by the trochlear surface of the talus, whereas in the ground-adapted pongids the laterally projecting fibular articular facets, with corresponding modifications of the fibula, indicate a lateral shift in the axis of weight transmission. When the canonical weights are examined for variate I, a long talar neck and an insignificant fibular facet are indeed parameters which discriminate between the quadrupeds and the knuckle-walkers.

In summary, this analysis confirms that these fossil tali are more like the tali of knuckle walkers than bipeds. As suggested by Oxnard, however, the similarity has been shown to be relative because finer locomotor discrimination reveals that the two fossil tali from Rusinga show a greater, and indeed significant, affinity with tali of the quadrupeds *Papio* and *Cercopithecus*. This confirms the earlier morphological assessment of Le Gros Clark and Leakey⁶ and suggests that the inclusion of these Miocene tali in the locomotor group represented by extant knuckle-walking pongids may be premature. Moreover, the behaviour of CMH 145 in the analysis is additional evidence for Pilbeam's contention⁷ that this specimen may belong to a different species from that of the tali from Rusinga.

I thank Professors E. H. Ashton and M. H. Day for their helpful comments, Mr G. B. Newman for continued statistical advice and Miss Leader for typing the manuscript.

BOOK REVIEWS

Primate Evolution

Evolution of Primates: An Introduction to the Biology of Man. By A. B. Chiarelli. Pp. xi+354. (Academic: New York and London, April 1973.) £7.20.

THE publishers announce this as "probably the only comprehensive treatment on primate evolution to be compiled", which is odd because Academic Press have recently issued a much more useful book on virtually the same subject^{1,2}; and most of the wide field approached by Professor Chiarelli is adequately covered in a well written textbook which has already seen several years of service³. It is, indeed, an enormous undertaking to deal with genetics (from the molecular level upwards), speciation, living and fossil primates and the emergence of man all in one volume. However, there is always the danger with such a wide-ranging approach that depth of treatment and command of theoretical issues will be wanting, and Professor Chiarelli has unfortunately failed to cope with the task that he set himself.

Although concerned with the central theme of primate evolution, there is no discussion in the text of the methods used to establish evolutionary relationships. The fundamental concepts of homology and convergence, for example, are left unmentioned. Instead, Chiarelli uses the simple model of the living primates as a graded series of arrested ancestral stages: "In fact, prosimians, monkeys and anthropoid apes may represent the survival of stages reached in the past by human ancestors". In line with this, it is also stated that "comparative anatomists and palaeontologists now generally agree that the tree shrew can serve, *cum grano salis*, as an example of the first phase of the evolution of the primates". First, it is a vast oversimplification to imply that tree shrews simply ceased to evolve some 70 million years ago. Second, it should at least be mentioned that several authorities⁴⁻⁷ have now rejected the hypothesis that tree shrews are related to primates.

Even if used as a model for primate evolution, tree shrews are of marginal importance; but it is nevertheless desirable to describe them accurately. Yet the fossil *Anagale*, which is in any case an unlikely relative of tree shrews^{8,9}, is vaguely referred to as "Oligocene fossil *Ptilocercus* from Mongolia". And when it is stated that the living tree shrews are "among the smallest existing mammals, very lively and aggressive,

and as their metabolic rate is very high they eat voraciously", it is apparent that Chiarelli has confused the Soricidae with the Tupaiidae. We are also told that the tree shrews have eyes "placed at right angles to each other".

Slips of this kind are, unfortunately, abundant. The aye-aye, for instance, is said to live on the juice sucked from sugar-cane, and this admittedly bizarre lemur is granted two different dental formulae on pages 59 and 157. We are informed that, for the lemurs in general, "their intellectual capacity has not increased during their evolution from the time they arrived in Madagascar", and it is stated that Palaeocene and Eocene fossil relatives have been found in Africa. Palaeontologists will also be surprised to see that the map of world distribution of fossil primates omits the entire New World.

Although the description of the better known simians is generally more accurate, it is unsettling to find that Chiarelli—apparently on the basis of superficial karyological and serological similarities—takes the unusual step of classifying the gibbon with cercopithecoïd monkeys rather than with the apes. Interpretation of similarities of this kind is by no means simple, and in an intended textbook such sweeping revision of a widely used classification deserves full discussion. In any event, on page 141 Chiarelli overlooks his revision and reverts to placing the gibbon (misprinted as *Hyloteles*) in the Hominoidea.

The sphere of hominid evolution fares no better. On page 236, a maxilla attributed to *Ramapithecus* is mislabelled and printed upside down, and Chiarelli states (perhaps through the agency of yet another misprint) that this genus displays the most hominoid characteristics within the dryopithecine radiation. With the later hominids, in spite of the fact that many recent authors have followed a greatly clarified scheme^{10,11}, Chiarelli revives the now obsolete proliferation of genus and species names. Apart from referring to *Homo erectus* exclusively as "*Pithecanthropus*" and to the *H. erectus*/*H. sapiens* transition stage as "*Protanthropus*", the term "*Palaeanthropus*" is used as if it were a genus name for forms which are also referred to as *Homo* species. Nowadays, this kind of confusion over nomenclature is only justifiable for forms of questionable taxonomic status, such as "*Homo habilis*"

from Olduvai; yet this particular form is totally omitted from the discussion of hominid evolution.

Chiarelli's primary research area is that of genetics and karyology, and chapters on these aspects to some extent compensate for failings elsewhere. Even these chapters, however, are not without serious faults. For example, the discussion of chromosomal evolution which is given with remarkable brevity in chapter 2 is not followed until chapter 11 with the actual evidence for primates. The resulting gap in the train of thought is compounded by errors of omission. There is no definition of metacentric or submetacentric chromosomes, though distinction of these from acrocentrics is fundamental to the understanding of chromosomal evolution. Again, Chiarelli resorts to the concept of arrested ancestral stages in referring to evolutionary processes: "In fact, although it is not possible to study the karyotype of the ancestors of living species, the study of the karyotype of the latter furnished many examples of the stages through which karyotypes have passed during their evolution".

Similar deficiencies occur in the treatment of genetics. For example, two maps (on pages 113 and 115) indicate totally different I^B gene frequency distributions in Europe for the ABO blood group system. It is also stated that "the number of amino acids which make up a protein normally does not exceed 20-25", which will misleadingly indicate to some readers that all protein chains are very short, rather than that there are usually 20-25 different kinds of amino acid involved. Again, a fairly competent description of haemoglobin evolution is spoiled on page 105 by confusion over mutation rates and misprinting of the Greek symbols for haemoglobin chains. Finally, for the really crucial developing issue of tree-building using basic biochemical data, the reader is supposed to decipher the following: "In fact, at first approximation, the amount of divergence between two species can be measured by counting the ratio of the number of homologues that have a different amino acid".

There is always a possibility that recitation of individual errors may mask the true merits of a book, and it must in all fairness be said that Professor Chiarelli has exhibited an enormous range of interests and a very broad (if inaccurate) spectrum of knowledge. Two facts are certain, however; treatment of some of the subjects indicates a quite inadequate grasp of the material, and the book as a whole has been pro-

duced with a surprising lack of attention to detail. There are numerous errors of fact, partly because of the large number of printing faults, and the translation is in places not entirely clear. Even the arrangement of the chapters seems to be somewhat haphazard ("The Concept of the Species" and "Evolution of Species" are unaccountably separated by "The Living Primates"). Finally, there is frequent omission of key references from the lists at the ends of the chapters, numerous figures are reproduced without acknowledgment of the source, and the index is insufficient. In short, in spite of the valiant attempt to cover an enormous field, this book is so poorly produced that it will merely serve to confuse students taking courses in primatology.

Predicting Technology

Technological Planning and Social Futures. By Erich Jantsch. Pp. xiv+256. (Cassell/Associated Business Programmes: London, March 1972.) £4.50.

THIS book is a masterpiece of overstatement. The author suffers a little from the illusion, common amongst enthusiastic proponents of complex management techniques, that the methods advocated are already successfully and widely practised in government and industry, or soon could be. Thus, for example, the book repeatedly refers to the experience of PPBS as though it played an extremely important part in the decision making of the United States government. No one would ever guess from this set of essays that the general experience of PPBS, however worthy the concept may be, has been one of disillusion, or that it has been largely discarded and down-graded. Even more important, it would apparently never occur to the author that there is more to be learnt about US policy making from the Watergate hearings than from PPBS or PERT.

Similarly, in the case of industry

there is a gross overestimation of the role of "technological forecasting." All the empirical evidence shows that its actual influence on decision making both in America and Europe today is very slight. Few firms employ "technological forecasters", and those which do, take their accountants' advice far more seriously.

Only when he reaches the level of world decision making does a greater degree of realism creep in, although even here Jantsch plays with the notion of the "world corporations" filling the vacuum of rational global policy making. By and large, however, he recognizes that nation states and international corporations do not at present adopt a standpoint of global responsibility, but one of self-interest. This leads him to a position of extreme pessimism, as he accepts uncritically the naïve models of Forrester on resource depletion, population and pollution. Chapter 14 is a reprint of his review of Forrester's book. Since he irritatingly equates "rationality" with the adoption of "system dynamics" by policy makers, it is hardly surprising that this chapter strikes a "Gottterdammerung" note markedly contrasting with the earlier chapters.

The style is somewhat ponderous and opaque. It compares in this respect rather unfavourably with the lucidity, scholarship and common sense of Vickers' discussion of similar problems, or Bright's clear, practical explanations or Gabor's lively normative approach to the choice of technology and future social change. Impatience with the unsatisfactory progress and narrowness of all the social sciences is quite understandable and legitimate, but Jantsch is too often inclined to substitute the box-diagram or the organisation chart. Not surprisingly, he has a considerable affinity with Forrester, the leading exponent of the universal application of system dynamics to social problems of all kinds. He shares with Forrester, too, an exaggerated respect for the capacity of American corporations to find solutions for social problems, whether at home or abroad.

All of which is a great pity, because underneath the jargon there is a nugget of gold. Whilst Jantsch suffers in full measure from some of the typical faults of the systems engineer in discussing social systems, his book also has the great virtues of this approach. He cuts through the trees and sees the wood as well. Many of his observations about policy making, new institutions and the complementary relationship of extrapolative and normative forecasting are extremely important.

Interdisciplinary research and functionally-based decision making are both highly desirable in many modern institutions. Although he exaggerates their

contemporary influence, some of the methods and reforms which he advocates are urgently needed. If he could summarize the main theme of these essays, and concentrate on the essential message, it would be a shorter book, but a much better one.

C. FREEMAN

Protective Mixture

Radiation Protection: A Guide for Scientists and Physicians. By J. Shapiro. Pp. xx+339. (Harvard University: Cambridge, Massachusetts; Oxford University: London, 1972.) £7.50 boards; £3.50 paper.

THE prospective author of a textbook or manual on radiation protection is required to provide a proper mixture of various disciplines and practices—physics, chemistry, biology, medicine, instrumentation, public relations, legislation and so on. To be truly comprehensive the mixture must be absolutely right but the author has a certain freedom in selecting the extent and the academic level of his compilation.

Dr Shapiro has aimed at a wide range of readers, including "physicians, research scientists, engineers and technicians". Part 1 is a historical prologue ranging from the primordial through the discovery of radiation to a statement of the need for radiation protection and the extraordinary measures—technical and legislative—that are necessary. Part 2 is offered as the core of the manual. It deals with the energy imparted by ionizing particles; with beta, gamma and other radiations; dose from external and internal sources and the significance relative to radiation standards, biological effects and natural background; and the calculation of radiation hazard. In the remaining parts (3-6) the following topics are covered successively: dose calculations; radiation measurements; protocol for users of radionuclides (necessary but hardly exciting); and considerations of public health (this provides valuable perspectives).

The coverage is complete, the style simple, the order logical and the whole easy to read. It is possible to criticize the disproportion in the treatment (under "Radiation Measurements") of G-M and scintillation counters (thirty pages) and that of ionization chambers (three pages). To test the academic level of this book I tried it on a young pre-university science student. He found the text intelligible and the calculations quite easy. He would have appreciated more rigorous mathematical treatments of some of the cases, inserted perhaps as appendices. This is a good manual, however, suitable mainly for the technician but with something in it for specialists from the other disciplines.

D. H. PEIRSON

NEW BOOKS FROM ELSEVIER

ATLAS OF THE TEXTURAL PATTERNS OF GRANITES, GNEISSES, AND ASSOCIATED ROCK TYPES

by **S. S. Augustithis**, Professor of Mineralogy, Petrography, Geology, National Technical University of Athens, Greece.

1973. 390 pages. Dfl. 160.00 (about US\$61.50)

The origin of granites has been a controversial subject for centuries. It is believed that a better understanding of the problem can only be achieved through observation of the textural patterns of rocks and their interpretation on the basis of the concept of comparative anatomy. With this in mind, the author has compiled an Atlas, containing 690 illustrations, which presents, compares and genetically interprets the most common textures in granites, gneisses and granitic rocks. It shows the wide spectrum of textural possibilities and their possible diverse origins.

THE RUGOSE CORAL GENERA

by **G. Cotton**, Blakedown, Kidderminster, England.

1973. 360 pages. Dfl. 130.00 (about US\$50.00)

For the first time condensed but complete diagnoses of Rugose Coral general and subgenera, and their type species, have been compiled in alphabetical order and in modern English terminology. The book is an up-to-date reference work and should be held by all major libraries, universities, geological surveys and prospecting companies throughout the world.

THEORY OF THE EARTH'S GRAVITY FIELD

by **M. Pick, J. Pícha** and **V. Vyskocil**, Geophysical Institute, Czechoslovak Academy of Science, Prague.

1973. 538 pages. Dfl. 96.00 (about US\$36.90)

CONTENTS:

Newton's theory of potential. Potential of some simple formations, approximate in shape to the figure of the earth. Equipotential surfaces. Reductions. Absolute gravity measurements. Relative measurements of the acceleration of gravity. Measurements of the second derivatives of the gravity potential. Some comments on the anomalous gravity field. Gravimetry and the internal structure of the earth. The geoid. Determination of the figure of the earth without considering hypotheses about its internal composition. Time variations of the gravity field. Observations of tides of the Earth's crust. Fundamental mathematical principles of gravimetric interpretation. Substitution of the Earth's body by a reference surface. Astronomical and astrogravimetric levelling.

THE OPAQUE MINERALS IN STONY METEORITES

by **P. Ramdohr**, Mineralogical and Petrological Institute, University of Heidelberg, Germany.

1973. 246 pages. Dfl. 65.00 (about US\$25.00)

The aim of this work is to provide a general survey of ore minerals occurring in stone meteorites. The author demonstrates that the investigation of carefully prepared polished sections is an excellent method of providing a clear picture of intergrowth structures. The book is based on the ore microscopic investigation of approximately 500 high-quality polished sections from 350 "falls". The results proved the subject to be far more complex than had been anticipated—15 of 35 different opaque components being completely new, with a further seven not previously known to occur in meteorites. Moreover, the existence (formerly doubted) of several ore minerals known only as extreme rarities has now been established.

GEOCHEMICAL TABLES

by **H. J. Rösler** and **H. Lange**.

1972. 468 pages. Dfl. 80.00 (about US\$30.80)

CONTENTS:

History, tasks, position and divisions of geochemistry. Fundamental chemical and physical concepts. Geochemical migration factors. Geochemical practice and testing methods. Representation and mathematical processing of geochemical data. Distribution of the elements in the cosmos and in meteorites. Distribution of the elements in the earth. Geochemistry of geologic-geochemical processes. Geochemical cycles and geochemistry of individual elements. Important fields of investigation of applied geochemistry. Units of measurement and miscellaneous.

The newest in genetics and ecology from Holt

GENETICS

by Ursula W. Goodenough and Robert Paul Levine, Harvard University
Written for a one semester course in genetics, this text covers both "classical" chromosomal genetics and "modern" molecular genetics. Each major subject is first considered as it applies to simple bacteria and viruses, and then to more complex, nucleate organisms. The beginning chapters focus on the five fundamental properties of genetic material. Succeeding chapters consider the experimental systems and procedures involved in studying gene transmission and in constructing genetic maps; functional interactions between genes and on genetic regulation, and genes in populations and the evolution of genes and species. Each chapter is abundantly illustrated with diagrams and micrographs and concludes with an extensive bibliography and problems.

January, 1974/896 pages/\$14.50

PAPERS IN BIOCHEMICAL GENETICS, Second Edition

edited by Geoffrey Zubay, Columbia University and Julius Marmur, Albert Einstein College of Medicine

Providing a broad, up-to-date treatment of DNA, RNA, and protein synthesis and its regulation, these 70 papers emphasize fundamental advances in the field of biochemical genetics. The editors have provided valuable discussions of the papers, which are a worthwhile compilation for all those interested in molecular biology and biochemical genetics. The number of readings has been expanded from 48 to 70 in this edition, of which only 12 papers appeared in the first edition. The authors have cited the most recent experimental papers or reviews in the introduction to each section, so the reader can locate earlier references to classical and related publications.

1973/640 pages/\$12.50/Paper

GENERAL ECOLOGY

by S. J. McNaughton and Larry L. Wolf, Syracuse University

Beginning with basic information, this text introduces students to ecology as an operating science with emphasis on data from the scientific literature. It explores ecosystems, populations, and community levels of organization, and provides evolutionary explanations for many ecological phenomena. The authors have integrated plant and animal ecology in such a way that the general application of ecological principles is apparent. No other book places as much emphasis upon the manner in which scientific principles are derived and supported.

1973/720 pages/\$13.00

THE ENVIRONMENTAL CHALLENGE

edited by Willis H. Johnson, Wabash College, and William C. Steere, New York Botanical Garden

This outstanding collection of fourteen articles is written as a supplementary textbook for introductory biology or environmental ecology courses. All but two of the articles were especially written for this collection by leaders in their respective fields. The articles include: basic background, problems of the human population, the major aspects of environmental pollution, the concentration of these problems in the urban area, what scientists and the government are doing to alleviate these problems, and a humanistic viewpoint on THE ENVIRONMENTAL CHALLENGE. A biographical sketch of each author is given and additional references may be found at the end of each article.

December, 1973/384 pages/\$6.00 (tent.)/Paper

Immunochemistry

Advanced Immunochemistry. By Eugene D. Day. Pp. xvi+447. (Williams and Wilkins: Baltimore, Maryland, 1972.) \$19.

As suggested by the title, some prior knowledge of immunology is required to appreciate this book fully. The first half of the book deals with the structure of antibodies under four headings—"Light Chains of Immunoglobulins", "Heavy Chains of Immunoglobulins", "Sizes and Shapes of the Immunoglobulins" and "The Antibody Binding Site". In each chapter the past work (particularly from the 1950s-1960s) is introduced and leads to our present state of knowledge (and problems). The second half of the book deals with the reactions of antibodies. Besides the expected applications of law of mass action to reactions of antibodies with haptens and multivalent antigens, there is a very well written and concise chapter on the active centres of multivalent antigens.

Obviously a book bearing this title and running for only 401 pages (exclusive of index) will leave out certain aspects of the subject. The author has pre-empted the words of the critic, however, by mentioning most of these in the last chapter. The first half of the book deserves unqualified approval for its concise and logical presentation of our knowledge up to about the beginning of 1971. It will be very welcome for final degree students specializing in immunology, for people who want their immunological knowledge brought up to date, and of course for PhD students for its review of the development of the various topics. The second half is not so impressive simply because most of the information is available in other books and the information it contains has been around for a longer period of time. But apart from a spelling mistake on page 391, it is a useful review of the subject.

C. A. KING

Sequencing RNA

Determination of Sequences in RNA. By G. G. Brownlee. (Laboratory Techniques in Biochemistry and Molecular Biology, Volume 3, Part I.) Pp. 265. Edited by T. S. Work and E. Work. (North-Holland: Amsterdam, 1972.) £13.30.

Nucleic Acid Sequence Analysis. By Stanley Mandeles. Pp. 282. (Columbia University: New York and London, February 1973.) £7.

In recent years great progress has been made in the field of nucleic acid sequencing. Besides the two classical techniques which opened the way to such studies, DEAE chromatography and the fingerprinting method, there are now many modifications in use for

investigating large RNA molecules. New approaches have also been introduced, based on copying *in vitro* RNA or DNA and combining the former analytical techniques with nearest neighbour determination and with kinetic analysis of synchronously synthesized fragments of RNA. The number of RNAs with at least partially known sequences is ever increasing and promising attempts have been made also to apply sequencing techniques to some DNA molecules. A comprehensive review in this field has indeed been needed for a long time and can be expected to be very helpful both to scientists familiar with some aspects of these problems and to those intending to start now nucleotide sequence analysis. It is therefore very welcome that two monographs on RNA sequencing have been published at approximately the same time.

Brownlee's book deals mainly with the two classical methods, Holley's column chromatography and Sanger's fingerprinting technique, and mentions briefly some new approaches involving *in vitro* labelling of RNAs. After a short introduction, he describes in detail the enzymic digestion and chromatographic fractionation techniques used in studying the structure of non-radioactive RNAs and the analytical methods for establishing the structure of the digestion products. Chapters 3-6 give a very comprehensive description of the fingerprinting technique, including technical details, alternative methods, diagrams showing the electrophoretic mobilities of different oligonucleotides and their degradation products. Chapter 5 is perhaps a too lengthy presentation of the sequencing of 5S RNA but it discusses also many modifications of the original technique and gives a useful illustration of the practical application of different analytical methods. Chapters 7 and 8 deal with some special problems, like minor bases and terminal sequences, while chapter 9 summarizes briefly some more recent methods involving *in vitro* labelling of RNAs.

Throughout the work the practical side of the problems is emphasized, and results are discussed only as far as they facilitate the understanding of the methods used. In addition, there is a very useful appendix, giving further details about the exact conditions for labelling, isolating, fractionating, digesting RNAs, mentioning even the suppliers of equipment, enzyme preparations and other special chemicals used. The book is certainly a very useful manual, enabling the reader to set up a suitably equipped laboratory and start sequence studies on RNA.

The intentions of Mandeles's book seem different. He reviews a much wider field of sequence work, covering

at least the principles of almost all techniques ever used for partial or total sequence determination. He even includes early approaches which had rather limited use and a chapter on physical methods which are at present not suited for sequence studies but might be further developed and possibly used in the future for such purposes. The first nine chapters describe the principle and occasionally also some practical details of all the sequencing methods applied to RNA; chapters 10 and 11 give practical description of several techniques used in RNA research, from isolation techniques of RNA to analysis of some small degradation products. The choice of techniques presented in this latter part is not very fortunate: some simple, widely known procedures are described in detail while some specialized techniques are mentioned rather briefly. The last chapter summarizes the results of RNA sequencing: the structures of a great number of RNAs, as known today, are shown.

As the first review covering this whole field the book is certainly of considerable interest. It is not very well suited, however, to be used as a manual or as a guide to find the best technique for a particular sequencing problem. This is partly because the practical information is sometimes insufficient, partly because different methods are not always critically compared and evaluated with respect to their application to different problems.

M. SZEKELY

Inorganic Systems

The Constitution of Inorganic Compounds: Atomic Quantum Mechanics—Metals and Intermetallic Compounds. By John L. T. Waugh. Pp. xv+797. (Wiley: New York and London, August 1972.) £12.50.

THIS is an immense book, but it is only the first of two volumes devoted to inorganic molecules and solids. This first volume concentrates on the fundamentals of quantum theory, so that by page 797 the reader has just been prepared for a subsequent study of inorganic systems. It is a pity that both volumes could not have been published simultaneously, for one could then see more clearly the rationale of the choices of topic in volume 1.

In brief the author presupposes no prior knowledge of quantum theory. He introduces it from scratch, developing the general principles of the wave equation, operators, mean values, particle-in-a-box, hydrogen atom, and so on, following rather standard analysis. There follow chapters on variation and perturbation methods, spin, and atomic structure. By now we are at page 379 and halfway through the book. The second half is devoted to the metallic

state, band structure, Brillouin zones and a little about intermetallic compounds.

This is a formidable amount of material, especially when one sees what the author means when he writes in the preface that he wants to discuss inorganic systems "without simply stating results". He has certainly achieved this aim: there are three pages showing line by line how to pass from Cartesian to spherical polar coordinates in the expansion of ∇^2 ; and there are four pages in small type working in detail through the Kronig-Penney model of a lattice.

It is impossible in a book of this kind to keep a uniform mathematical level. Thus the calculus of variations, which is hard, comes on page 103, just ten pages before the use of an Argand diagram, which is easy. There does not seem to be much that is wrong, though someone new to the Dirac δ -function might be surprised to see it defined (page 131) by $f(x) = \int f(x) \delta(x-x) dx$. Almost inevitably there is a certain inelegance when so much ground has to be covered (for example, the proof of the Uncertainty Principle on page 158).

On the good side it must be said that most of the mathematics really is clear, and the diagrams are excellent, so that if a student were to take up this book and work steadily through it, without any doubt he would be able to learn a lot. It would be an excellent book, not so much for class use, but as a reference volume to which a student could be referred if he found his class lectures unpalatable. C. A. COULSON

Ornithological Statistics

The Visible Migration of Birds at Ottenby, Sweden. Edited by Carl Edeltam. Drawings by Harald Wiberg. Pp. 360. (Swedish Ornithological Association: Stockholm, 1972.) 95 Sw. cr.

THIS is an extraordinary book in several senses of the word. Teams at many bird observatories have counted the birds daily migrating past. In the few cases where analyses have been published it is usually stated that the original data have been deposited at some institute. The Ottenby team decided that this was not good enough and have deposited the original data in the reader's lap. Interpretation and commentary occupy less than a fifth of the book—a tenth, really, since each page is half English, half Swedish.

The data concern ten years, 1947 to 1956, June to October, and 1,509 observation days. The yearly totals for sixty species are presented in the form of histograms elegantly spaced over ten pages. These are then re-sorted into a further set of 10-day period histograms. Then the daily totals for each species

for each year are set out, again as histograms, over 180 pages. The monotony of page (36×22.5 cm) after page of black bars and white space is offset by an elegant line drawing of each species.

Next the hourly variations within each 10-day period are presented in the form of two seven-step ladders, on the rungs of which the histograms are mounted. The extravagance of the layout is even more apparent here, for in half the 70 species given a page apiece, the left or right hand ladder is completely empty.

The production is impeccable, the paper quality high, the draughtsmanship superb, the amount of work appalling. Yet what does it achieve? Certainly, as pointed out in the commentaries, impressions can be gained by visual inspection, but to test them recourse to the original numerical data is still needed. These could be extracted by measurement (the histograms are meticulously accurate) but it would have been simpler (and not much duller) to have the numbers themselves, and to use histograms to illustrate particular points that statistical analysis had shown to be valid.

There is little doubt that this book will remain unique. A wide sale cannot be forecast. G. V. T. MATTHEWS

Geometrical Optics

The Optics of Rays, Wavefronts and Caustics. By O. N. Stavroudis. Pp. xvi+313. (Academic: New York and London, October 1972.) \$18.

THIS interesting and unusual book on geometrical optics begins (after an historical introduction) by obtaining the concept of a ray path in a medium of continuously varying refractive index via the calculus of variations, and continues with an account of the differential geometry of curvature and torsion of generalized space curves. Then the Hilbert integral is defined and used to deduce the mathematical concepts of the wavefront as a transversal of a two-parameter family of rays and the caustic as the envelope of such a family. Snell's law is then derived for a medium of sectionally-continuous refractive index.

Contact with the bread-and-butter of geometrical optics is made in a discussion of ray tracing, but the treatment is at an esoteric level with no real mention of how to do ray tracing in cases of practical interest. It is probably fair to assume, however, that no neophyte in need of such advice would buy the book anyway.

Chapter seven establishes the general condition for the existence of a wavefront to a set of rays and Malus's theorem is formally proved. The chapter on "Generalized Raytracing" concerns the propagation of an element of wavefront through a system and represents, in effect, a generalized paraxial

ray trace in which the optical axis is replaced by a skew finite ray.

The discussion on classical aberration theory includes Hamilton's characteristic function, Hertzberger's diappoint theory, and an incomplete account of the Seidel aberrations. This is preceded by a partially successful attempt to produce the reverse of the well-known Luneburg derivation of the fundamental properties of geometrical optics from Maxwell's equations.

A radically different mechanism of image analysis is then studied in the form of Hertzberger's fundamental optical invariant and its scalar form the lens equation. This is a system of first-order partial differential equations involving ray coordinates and directions at the object and image planes. The book closes with a closely-reasoned but slightly tongue-in-cheek application of algebraic group theory to lenses—heady stuff for lens designers.

In summary, there is little in the book to cause the designer to rush to the coding sheet to rewrite his programs—it is not a book of that level. But for those of us who enjoy an occasional dip into the rigours of Luneburg there is much here to interest and stimulate, and the author succeeds in guiding us through the welter of mathematics with an entertaining and readable style. JOHN MACDONALD

CORRESPONDENCE

Misidentification or Misunderstanding?

SIR,—The article 'Misidentified Dyke' (*Nature*, 244, 485; 1973) by your geomagnetism correspondent contains the following inaccuracies. (1) The trend of the Wackerfield Dyke is ENE not WNW (Fig. 1). It is important because dyke trends in Northern England have long been recognised as reliable indications of age, WNW for Tertiary and ENE for late Carboniferous (called Carboniferous-Permian before the advent of radiometric age determination). (2) It is not therefore "fairly obvious from field relations that it forms part of the Cleveland-Armathwaite Dyke"; their outcrops are near but their trends are different. The original statement by Tarling *et al.*¹ that "its field relations suggest that it could be part of

the Cleveland-Armathwaite Dyke" is only slightly less misleading. (3) Tarling *et al.* do not claim that the dyke has "always been regarded as part of the Tertiary activity", nor do I know of a publication which does. On the contrary it is unequivocally grouped with the dykes associated with the Upper Carboniferous Whin Sill and equally unequivocally differentiated from the Tertiary Cleveland Dyke in the standard petrographic studies of Holmes and Smith² and Holmes and Harwood³—both quoted by Tarling *et al.* It is also clearly shown as of 'Carboniferous-Permian' age on the Geological Survey one-inch map (Sheet 32: Barnard Castle) published in 1969.

The work of Tarling *et al.* thus con-

firms "long cherished beliefs" rather than requires that they should be discarded. In case it is overlooked, it may be as well to emphasise the real contribution made by Tarling *et al.*—namely the relevance of palaeomagnetic studies in establishing the age of emplacement and subsequent history of intrusions like the Wackerfield Dyke.

Yours faithfully,

D. A. C. MILLS

*Institute of Geological Sciences,
Ring Road, Halton,
Leeds LS15 8TQ*

¹ Tarling, D. H., and Mitchell, J. G., *Earth planet. Sci. Lett.*, 18, 427 (1973).

² Holmes, A., and Smith, S., *Geol. Mag.*, 58, 440 (1921).

³ Holmes, A., and Harwood, H. F., *Mineralog. Mag.*, 21, 493 (1928).

Our Geomagnetism Correspondent writes:

Dr Mills is quite right; I have misunderstood. I measured the trend of the Wackerfield Dyke from the Tarling *et al.* map which, because of its small scale, led to the ambiguity now resolved by Dr Mills' larger scale version. Once this point is cleared up, and accepting the points made by Dr Mills in (3) above, it becomes difficult to understand why Tarling *et al.* should say that "its (the Wackerfield Dyke's) field relationships suggest it could be related to the Eocene Mull Dyke Swarm"—a misleading statement which, compounded by my error in the trend, I am guilty of accepting rather too uncritically.

Obituary

Professor Jean Hanson

Professor Emmeline Jean Hanson, FRS, Director of the Medical Research Council's Muscle Biophysics Unit at King's College London, died on August 10 of an acute meningococcal infection, at the age of 53.

An only child, she was born in Derbyshire, and was educated at the High School for Girls, Burton-on-Trent, and

at Bedford College in the University of London. After taking her BSc in Zoology, she was engaged in cancer research for two years at the Strangeways Research Laboratory, Cambridge, producing two papers on the histogenesis and differentiation of the mammalian epidermis. She then returned to Bedford College in 1944 with a teaching appointment in the Zoology Department, making a number of histological

and other investigations on several aspects of structure and function in annelids.

The decisive step in her scientific career was her appointment in 1948 to the Biophysics Research Unit, established by the Medical Research Council in the previous year under Sir John Randall, then Wheatstone Professor of Physics at King's College London. She and Randall were put in touch by

Munro Fox, the Head of her Department at Bedford College, and the appointment was as significant for the unit as it was for her. Her wide knowledge of biology was an important factor in a unit where other members had almost all been trained in the physical sciences, and her personal qualities—her energy, her integrity and her helpfulness to others—contributed greatly to the successful development of the unit. The investigations on muscle, which later became one of the chief interests of the unit, were centred on her from the beginning. For the first few years she was the only member of the unit working on muscle, but under her inspiration this side of the unit's activity expanded so that, when the unit was divided after Randall's retirement in 1970, one part became the Muscle Biophysics Unit, and she was appointed as its Director.

Although she held a full-time research appointment, she devoted a large part of her energy to undergraduate teaching at King's College. Not only did she develop courses in Biophysics, both within King's and as part of the inter-collegiate teaching of London University, but she played a key part in the development of the School of Biological Sciences at King's. She often acted as an external examiner, both for undergraduate examinations and for doctoral theses, and made a reputation for sympathetic and conscientious work in this capacity. In 1966, the University of London conferred on her the title of Professor of Biology.

From the time when she first joined Randall's Biophysics Research Unit, almost all of her research was concerned with the structural basis of muscular contraction, and it is for this that she will chiefly be remembered. Her first

attempts at elucidating the changes in the striation pattern during contraction, published in 1952, showed the formation of contraction bands but threw no light on the earlier stages of shortening. Her method, however—observing separated myofibrils under a phase-contrast microscope—was used again by her with great success in a period of highly fruitful collaboration with Dr H. E. Huxley. This began in 1953–54, when both of them spent the year in the laboratory of Professor F. O. Schmitt at the Massachusetts Institute of Technology, she as a Fellow of the Rockefeller Foundation. They first established the localisation of myosin and actin in the striation pattern (also done independently at the same time by W. Hasselbach in H. H. Weber's laboratory) and soon afterwards showed the constancy of the distances in the striation pattern corresponding to the lengths of the thick and thin filaments. This was paralleled in part by A. F. Huxley and R. Niedergerke's measurements on living fibres. Together with H. E. Huxley's evidence from electron microscopy and X-ray diffraction, these results formed the chief basis of the sliding filament theory, now universally accepted.

Her later work, much of it in collaboration with Professor J. Lowy, was almost all carried out with the electron microscope. Most of it was related to two problems: the structure of muscles of molluscs and other invertebrates, and the structure of the thin filaments. Hanson and Lowy were the first to obtain isolated thin filaments, and these showed clearly the helical arrangement of the actin monomers. Later work, on which she was still engaged at the time of her death, was concerned with the position of other components of the thin fila-

ments, tropomyosin and troponin.

Aside from her own investigations, she played a very great part by inspiring the muscle team that she gradually built up. Her name appeared on papers only when she had actually taken a major part in the experimental work, but all the other work from the unit, whether electron microscopy, X-ray diffraction or protein chemistry, owed a tremendous amount to her interest, encouragement and criticism, and to her wide knowledge both of the muscle field and of biology in general. Under the influence of her personality, the unit became an exceptionally happy place, where there was excellent cooperation between the members, and where visitors were made welcome.

She was elected to the Royal Society in 1967. She was outstandingly friendly and helpful towards everyone she had to do with, and will be deeply missed by a wide circle of scientific colleagues and other friends. She was unmarried.

Evolutionary Paleoecology of the Marine Biosphere

By James W. Valentine, The University of California
at Davis

New! **Evolutionary Paleoecology of the Marine
Biosphere** is possibly the most important book in
the field in 20 years. Designed as a reference and
advanced text for paleontologists, stratigraphers,
biologists, and for courses in Advanced Paleontol-
ogy, Evolution, and Biogeography.

This new book presents an integrated theoretical
framework of biological aspects of the marine
fossil record, tracing and interpreting the
processes of evolution and ecology. A most in-
formative book for professionals, students and the
general reader. September 1973, 512 pp., illustra-
ted \$12.95

A PLUG FOR OUR β -COUNTER

Anyone on your staff can operate the LKB-Wallac Liquid Scintillation Counter as a routine laboratory instrument. All they have to do is pick out two plug-in boards programmed for the particular samples, plug them in and press the Start button. The counter does the rest, and even gives a confirming printout of the selected parameters.

You avoid repeating all the work of selecting windows and calculating optimum parameters each time you change from one type of sample to another. **Do it only once.** The information is stored on the plug-in boards ready for use on the next occasion.

The LKB-Wallac system can be used both for single and double labelled samples, to give printouts of CPM and true DPM. An extra unit, which plugs in on top of the main control panel, converts the instrument for multi-user and double labelled operation.

APPOINTMENTS VACANT

AGRICULTURAL RESEARCH COUNCIL POULTRY RESEARCH CENTRE

Applications are invited for a post within the Scientific/Higher Scientific Officer grades in the Ethology Section of the Poultry Research Centre for work on animal welfare and stress.

Candidates should have a good Honours degree (and preferably a Ph.D.) in a biological subject and be interested in studying physiological changes accompanying frustration and conflict. Some knowledge of the preparation of data for computer analysis and of electronics would be an advantage, since the work will initially entail use of telemetry.

Salary within the scales £1,318 to £2,177 or £2,076 to £2,667 per annum with placement according to qualifications and experience. F.S.S.U. superannuation with a non-pensionable allowance to offset contributions.

Application forms, which may be obtained from the Secretary, Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh EH9 3JS, should be completed and returned to him not later than November 15, 1973. (1306)

AGRICULTURAL RESEARCH COUNCIL POULTRY RESEARCH CENTRE

Applications are invited for a post within the Scientific Officer grade in the Nutrition Section of the Poultry Research Centre. The person appointed will be in charge of a small team and be responsible for all records of nutrition experiments, which include food consumption, liveweight, egg production and hatchability. The team also carry out carcass processing.

Qualifications: A pass degree, H.N.C. or equivalent in the general field of agriculture. A knowledge of poultry husbandry is desirable.

Salary: Within the scale £1,318 to £2,177 per annum with placement according to qualification and experience. The post is superannuable with an allowance to offset contributions.

Application forms, which may be obtained from the Secretary, Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh EH9 3JS, should be completed and returned to him not later than November 16, 1973. (1344)

MEDICAL RESEARCH COUNCIL

SCIENTIST required for the Secretariat of the Committee on Protection against Ionising Radiations. Duties include the reporting and organising of meetings, appreciation of current literature on a wide variety of topics in biology, medicine, and physics. There would be opportunities for theoretical, experimental or epidemiological work on the relationship between effects and dose of ionising radiation. The successful candidate would be located at the Radiobiology Unit at Harwell and would enjoy M.R.C. conditions of service and Grade II salary scale up to £3,378 per annum according to age and any relevant experience.

Applications should be addressed to: The Administrator, M.R.C. Radiobiology Unit, Harwell, Didcot, Berkshire, to reach him by November 30, 1973. Please quote Reference RDB/35. (1399)

BOTSWANA CHEMIST (Geological Survey)

Required to analyse ores, rocks, minerals, silicates and underground water, and train and supervise laboratory staff.

Male candidates only, between 25 and 50 years of age, MUST have a degree in Chemistry, or licentiate or graduate membership of R.I.C.; or Higher National Certificate in Chemistry, and at least five years' approved and relevant experience biased towards analytical, geological or inorganic chemistry.

Commencing gross salary according to experience in scale equivalent to £1,780 to £4,450 a year. A substantial Gratuity is payable on completion of engagement which is for one tour of 2½ years initially.

Because of lower rates of income tax in Botswana the gross emoluments are roughly equivalent to U.K. salaries of:

£2,650 to £5,550 for a single man;

£3,600 to £6,650 for a married man with two children.

Other benefits include free passages, liberal leave on full salary, generous education allowances and Government quarters at moderate rental. Appointment Grant up to £200 and Car Advance £600 may be payable.

The post described is partly financed by Britain's programme of aid to the developing countries administered by the Overseas Development Administration of the Foreign and Commonwealth Office.

For further particulars you should apply, giving brief details of experience to:

crown agents

ARCHIFAR A Pharmaceutical Industry

has a vacancy at the new Research Laboratories in Northern Italy for a

MICROBIOLOGIST

He will be engaged in research on ANTIBIOTICS and ENZYMES. Applicants must have at least 4 years of post-graduate experience in the field. Applications which should include comprehensive curriculum vitae and addresses of two referees, should be sent to:

Archifar S.p.A., Via Trivulzio, 18, 20146 Milan, Italy.

(1387)

Senior Physicists step into space

Our involvement in a major space project, requires the leadership of a man who can bring heavyweight experience and effort in the field of physics. Following the launch of two highly successful Infra Red Temperature Sounding Radiometers in 1970 and 1972, we are responsible for the Stratospheric Sounding Radiometer of Tiros 'N', the first of a series of fully operational meteorological data gathering satellites. If you are interested and have a good honours degree in physics, possibly a higher degree, tempered by about 5 years' research and development experience in most of the following: Radiometry, Optics, Infra Red Detection, High Vacuum or Thermodynamics we would like to hear from you. At the same time, Physicists with less experience would be considered for a variety of other openings in this pioneering work. Salaries are negotiable and assistance with re-location expenses will be given where appropriate. Write giving comprehensive career details to John Fell, of our Advanced Projects Group, Marconi Space and Defence Systems Limited, Chobham Road, Frimley, Camberley, Surrey. Or telephone Camberley 63311. Ext. 206.

A GEC-Marconi Electronics Company

(1457)

UNIVERSITY OF KHARTOUM SUDAN

Applications are invited for post of PROFESSOR/ SENIOR LECTURER/LECTURER IN ENGINEERING MATHEMATICS in the Department of Engineering Mathematics, Faculty of Engineering and Architecture. Salary scales: Professor £53,600 per annum, Senior Lecturer £52,400 to £52,800 per annum, Lecturer £51,500 to £52,300 per annum. The British Government may supplement salary in range £1,300 to £1,800 per annum (sterling) for married appointee or £800 to £1,000 per annum (sterling) for single appointee (normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages: various allowances; superannuation scheme; annual overseas leave.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail not later than November 29, 1973, to the Personnel Secretary, University of Khartoum, P.O. Box 321, Khartoum, Sudan. Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars are available from either address. (1360)

UNIVERSITY OF WINDSOR WINDSOR, ONTARIO, CANADA

Applications are invited for:

HEAD DEPARTMENT OF BIOLOGY

Applicants are expected to have a distinguished record in research and teaching. Duties include: administration of a sixteen member department which offers undergraduate and graduate courses (through doctoral level) in a broad spectrum of biological sciences; fostering the development of research programmes; and participation in research and teaching.

The appointment commences July 1, 1974. Salary to be negotiated according to qualifications and experience.

Please send application, curriculum vitae, names of at least three referees and other pertinent information to:

Chairman of Selection Committee,
Department of Biology,
University of Windsor,
Windsor, Ontario, Canada.

(1310)

UNIVERSITY OF MANCHESTER LECTURER IN VIROLOGY

Applications invited for this post from candidates with or without medical qualifications. Salary ranges per annum: (clinical) £2,535 to £5,361; (non-clinical) £1,929 to £4,548. F.S.S.U.

Further particulars and application forms (returnable by November 30) from the Registrar, The University, Manchester M13 9PL. Quote Ref. 191/73/Na. (1351)

CHAIRMAN—DEPARTMENT OF ANATOMY

Columbia University, College of Physicians and Surgeons, an equal opportunity employer, is seeking an individual as Chairman of Anatomy Department. Should be qualified medical scientist and experienced medical educator.

Send curriculum vitae to: Myron Winick, M.D., Chairman, Search Committee, Institute of Human Nutrition, 511 West 166th Street, New York, New York 10032. (1289)

UNIVERSITY OF LONDON KING'S COLLEGE

LECTURER IN PLANT SCIENCES

Applications are invited for the post of Lecturer in Plant Sciences, tenable from April 1, 1974, or as soon after as possible. Applicants must have a good Honours degree, and an interest in phytochemistry and its application to systematic and/or ecological problems would be an advantage. Salary scale £1,929 to £4,548 plus £162 London Allowance (starting salary according to qualifications and experience). F.S.S.U. pension scheme.

Application forms and conditions of appointment may be obtained from the Registrar (N), King's College, Strand, London WC2R 2LS, and must be received by November 23, 1973. (1358)

UNIVERSITY OF GLASGOW S.R.C. RESEARCH ASSISTANTSHIP IN POLYMER CHEMISTRY

A vacancy exists for a Research Assistant in Polymer Chemistry, a post financed by S.R.C. through funds available to the Glasgow Polymer Centre. The appointment (which may commence at any time up to January 1, 1974) is initially for one year, with the possibility of extension for a further two years. The salary will be in the region of £1,900 to £2,000 plus F.S.S.U. The person appointed would be expected to carry out research work in the field of degradation of polymer blends or of block or graft copolymers, and might be asked to make a minor contribution to the teaching of the Department.

Applicants should send full details of their qualifications (for which the minimum requirement is a Ph.D. degree or its equivalent) and research experience, together with the names of two referees, to Professor N. Grassie, Chemistry Department, University of Glasgow, Glasgow G12 8QQ, Scotland. In reply please quote Ref. No. 3375. (1370)

RESEARCH TECHNICIAN

required for English-speaking molecular biology department in modern research institute involved in study of viral transformation of animal cells in culture. Experience with general biochemical techniques in enzymology and subcellular fractionation and with general sterile techniques associated with tissue culture useful. Salary on BAT scale from DM14,600 to DM17,880 per annum, according to experience, plus family allowances.

Applications, with the names of two professional referees, should be sent to Dr. D. Jovin, Abt. Molekulare Biologie, Max Planck-Institut für Biophysikalische Chemie, 34-Göttingen-Nikolausberg, POB 968, W. Germany. (1297)

UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY

A vacancy occurs for a LECTURER with an interest in molecular aspects of pharmacology to participate in the teaching of pharmacology and biochemical pharmacology in the undergraduate and postgraduate courses in biochemistry, nutrition, toxicology and other medical sciences.

The candidate, who may be a graduate of biochemistry, pharmacology or medicine, will be expected to participate actively in research and in liaison with industry. Appropriate research and industrial experience will be considered advantageous.

Salary will be on the scale £1,929 to £4,548 with F.S.S.U. provision.

Further particulars may be obtained from the Academic Registrar (LFG), University of Surrey, Guildford GU2 5XH, telephone Guildford 71281, extension 452. Applications, in the form of a curriculum vitae, together with the names and addresses of two referees, should be sent to the same address by Monday, December 3, 1973. (1376)

Centre for Overseas Pest Research

Deputy Director £6982-£7825

The Centre is a research, training and technical assistance unit concerned with pests of international or regional significance. Its main fields are pre-harvest pest and vector control in agriculture and public health in developing countries. Employing 150 people—90 of whom are qualified scientists—it carries out biological, ecological and control systems research, working closely with relevant organisations at home and overseas in the application of this knowledge to develop practical pest management systems.

The Deputy Director will be responsible for the day-to-day running of the Centre and will be involved with major policy formulation, in liaison with other O.D.A. departments, U.N. agencies, international organisations

and overseas governments. There will be extensive travel abroad.

Candidates must have a 1st or 2nd class honours degree in an appropriate subject and research experience, backed by considerable relevant practical and administrative experience.

Starting salary will be within the quoted scale.

Non-contributory pension scheme.

Fuller details of this appointment may be obtained by writing to the **Civil Service Commission, Alencon Link, Basingstoke, Hants., RG21 1JB**, or by telephoning **BASINGSTOKE 29222 ext. 500** or **LONDON 01-839 1992** (24-hour answering service), quoting **S/8421/U**. Closing date **31 December 1973**.

Overseas Development Administration

(1452)

McMASTER UNIVERSITY VIROLOGIST

A position is available for a Virologist at the Assistant or Associate Professor level. The appointee will be part of a viral oncology group being formed at McMaster University as well as a member of the Department of Biology. His/her research interests should be the molecular biology and/or genetics of animal viruses. His/her primary responsibility will be research and supervision of graduate students.

Applicants should send their curricula vitae and the names of three referees to the Chairman, Department of Biology, McMaster University, Hamilton, Ontario L8S 4K1, Canada, to arrive no later than January 15, 1974. (1381)

A NEW MEDICAL SCHOOL AT MEMORIAL UNIVERSITY OF NEWFOUNDLAND, ST. JOHN'S, NEWFOUNDLAND, CANADA

is expanding its faculty and is now ready to make appointments in the field of cell sciences. New buildings to house the cell sciences research group, which is part of the larger division of cell studies, will be ready for occupancy by 1975. The health sciences complex now under construction is a medical school with extensive research areas plus a biomedical library and 400-bed hospital.

Applications are now invited for a senior level position who would be able to organize a research team and participate in the inter-disciplinary teaching of medical students.

Interested individuals should submit applications, accompanied by a detailed curriculum vitae, to Professor B. H. Sells, Ph.D., Chairman, Search Committee, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland, Canada. (1382)

CHELSEA COLLEGE UNIVERSITY OF LONDON

TECHNICIAN GRADE 2B required for teaching laboratories dealing with the extraction of materials of medical importance from plants. Good working conditions. Salary scale £1,699 to £1,969 (including London Allowance).

Application forms from Manager of Technical Services (N), Department of Pharmacy, Chelsea College, Manresa Road, London SW3 6LX. (1392)

EAST MALLING RESEARCH STATION ASSISTANT STATISTICIAN

The Computing Unit requires an Assistant Statistician to undertake the processing of data from agricultural experiments.

The minimum qualification is a degree, H.N.C. or equivalent in a relevant discipline.

The appointment will be in the grade of Scientific Officer (£1,318 to £2,177), starting salary depending on qualifications and experience. It will be for three years, but may be extended.

Application forms and further details from the Assistant to the Secretary, East Malling Research Station, East Malling, Maidstone, Kent. (1393)

NATURE CONSERVANCY COUNCIL

Design and exhibition opportunities

There are 2 posts at Attingham Park, near Shrewsbury, within a small team concerned with publication, displays and other interpretative work.

The duties of the first post will include advising on design, illustration and layout, contracting out and supervising the execution of specific projects. Candidates must have an up-to-date knowledge of design precepts and techniques, and of sources of material and services. Experience in photographic and audiovisual techniques and some knowledge of natural history would be advantageous.

The second post is concerned with organising the exhibitions programme, selecting material, contracting out and supervising projects, arranging storage, distribution and maintenance of displays. Relevant experience is essential; an appropriate qualification and some knowledge of natural history desirable.

Starting salary may be above the minimum of the scale £2445-£2961. Promotion prospects: Non-contributory pension scheme.

For full details and an application form (to be returned by 21 November 1973) write, quoting **G(14)/634**, to the Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

(1354)

THE MEDICAL COLLEGE OF ST. BARTHOLOMEW'S HOSPITAL WEST SMITHFIELD, EC1A 7BE

Applications are invited for three posts of **LECTURER IN PHYSIOLOGY**, tenable from January 1, 1974. Salary scale £1,929 to £4,548 per annum, plus £162 London Allowance and membership of the F.S.S.U.

Forms of application may be obtained from the Secretary of the Medical College, and should be returned to the Dean not later than November 30, 1973. Further particulars may be obtained from the Department of Physiology. (1384)

ROYAL HOSPITAL FOR SICK CHILDREN

GRADUATE AS TECHNICIAN to join a group involved in the diagnosis and investigation of inborn errors of metabolism. The appointee would be responsible for lysosomal enzyme assays on cultured and uncultured cells. Previous experience not essential as full training will be given. Salary scale £1,390 to £2,292.

Applications, in writing, together with names and addresses of two referees, to the Secretary, Royal Hospital for Sick Children, 1 Rillbank Terrace, Edinburgh EH9 1LN. (1364)

ITALY

Important Italian Chemical Pharmaceutical Industry, with headquarters in Milano, operating at international level, seek

Head of Chemical Research

The successful candidate will work in the Research Department, will be an organic chemist, experienced in medicinal chemistry, creative-minded and with organisation capabilities.

His responsibilities will involve:

planning and directing the research of a team of experienced organic chemists for the scope of designing and synthesizing new therapeutically active molecules.

co-ordinating chemical research with pharmaco-biological screening of the new substances.

The position offers the candidate the possibility to develop his scientific personality within a Company that are leaders in pharmaceutical research. Knowledge of Italian would be an advantage.

Salary according to qualifications and in any case attractive.

Please send detailed curriculum vitae and salary requirements (for further transmission to the advertiser) first to:

SE/6647 Advertising Agency Dr Giuliano Blei, 8 Piazza del Liberty, I-20148 Milano (Italy).

(1407)

The United Sheffield Hospitals

A vacancy exists, for a period of 3 years, in the Transplantation Unit and Department of Urology, Royal Hospital, Sheffield, for a

Non-Medical Scientific Officer

to take part in a current experimental study into Transplantation of Islets of Langerhans in animals with a view to treating Diabetes. The work offers new avenues in the possible management of this condition.

Candidates should possess a 1st or 2nd class Honours degree in an appropriate subject (e.g., Zoology, Biochemistry, Physiology, Biology). The research offers an opportunity for acquiring a higher qualification. Whitley Council Conditions of Service apply. Salary Scale £1,566-£1,980 p.a.

Applications, stating age, qualifications and experience and naming two referees to: The Acting Chief Administrative Officer, United Sheffield Hospitals, 10 Beech Hill Road, Sheffield S10 2RZ, by 17th November, 1973. Further details supplied on request.

(1418)

UNIVERSITY OF MANCHESTER DEPARTMENT OF ZOOLOGY RESEARCH ASSISTANT IN CYTOLOGY

Applications invited for this post (funded by the O.D.A.) for research connected with tsetse fly and trypanosome control, involving the investigation of DNA/RNA synthesis during gametogenesis, oogenesis and vitellogenesis, and the cytogenetics of species, hybrids and radiation induced mutants. Post tenable until September 30, 1976, with an initial salary up to £2,058 per annum rising to £2,388 per annum. F.S.S.U.

Detailed applications, with names of two referees, should be sent to Dr. D. I. Southern, Department of Zoology, The University, Manchester M13 9PL, as soon as possible. (1404)

CHARING CROSS HOSPITAL (FULHAM)

FULHAM PALACE ROAD, HAMMERSMITH W6
DEPARTMENT OF MEDICAL ONCOLOGY

GRADUATE BIOCHEMIST required as part of a team isolating tumour antigens for immunodiagnosis. Experience in protein chemistry, immunochemistry, or in tissue culture work required. Suitable candidates have opportunity for Doctorate studies.

Salary on scale £1,404 to £2,496 (inclusive of London Weighting) according to qualifications and experience.

Please send curriculum vitae, with names and addresses of two referees, to Miss Matthews, Personnel Department, quoting Ref. 963, by November 9. (1375)

WEED RESEARCH ORGANIZATION Begbroke Hill, Yarnton, Oxford OX5 1PF

The Agricultural Research Council require a SCIENTIFIC OFFICER or HIGHER SCIENTIFIC OFFICER for a NEW POST in the Information Department of the Weed Research Organization (WRO) near Oxford. Duties include provision of scientific secretarial and editorial services associated with the varied commitments of the institute. Notably, help is given to the British Crop Protection Council in the organization of the scientific programmes of weed control conferences and technical symposia and in the compilation and editing of the Weed Control Handbook and other publications.

Within WRO the officer will serve as scientific secretary to committees responsible for the planning and co-ordination of the research programme. Assistance is also required in editing WRO publications and undertaking a variety of other information activities.

QUALIFICATIONS: Science degree or equivalent and interest in agriculture, with experience in scientific writing and the administration of technical committees. Ability to drive a car essential.

SALARY: Scientific Officer Scale (£1,318-£2,177 p.a.) or Higher Scientific Officer Scale (£2,076-£2,667 p.a.) depending on qualifications and experience, a minimum of five years' post-qualifying experience being required for appointment in the higher grade.

The post is superannuated with contributions off-set by a non-pensionable allowance of 5½ per cent of gross salary.

Application forms and further particulars available from Secretary, Weed Research Organization, Begbroke Hill, Yarnton, Oxford OX5 1PF. Telephone Kidlington 3761. Closing date for applications November 30, 1973. (1394)

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS AL5 2JQ

SCIENTIFIC OFFICER to assist with the study of soil minerals by physico-chemical methods including spectrometric analysis and X-ray diffraction. Minimum qualifications: pass degree, H.N.C. or the equivalent in chemistry. Starting salary £1,318 to £1,590 according to qualifications and experience on a scale to £2,177. Superannuation with allowance to offset contributions.

Applications, naming two referees and quoting Reference 2002, to the Secretary by November 30, 1973. (1397)

UNIVERSITY OF THE SOUTH PACIFIC—SCHOOL OF NATURAL RESOURCES

Applications are invited for the post of LECTURER IN BIOLOGY in the School of Natural Resources at the University of the South Pacific for appointment early in 1974. The vacancy is for a Population Ecologist. Preference will be given to an applicant with a Ph.D. and whose main interests are with either Microbial or Vertebrate Populations. The successful applicant will be required to conduct lectures, laboratories and tutorials at all levels of the degree programme and will be encouraged to contribute to advanced teaching and research within his own area of specialisation.

Salary in scale \$F4,700 to \$F200 to \$F6,300 (Lecturer scale) placing in accordance with qualifications and experience. Note: this salary scale is under review. (£1 sterling=\$F1.88.) 10 per cent annual gratuity for contract appointment, superannuation contributions, partly furnished accommodation at rental of 15 per cent of salary, appointment allowance. Contracts may be for two, four or six years.

Details of form of application, further particulars, and outline of terms of service are available from the Registrar (Post 73/50), University of the South Pacific, P.O. Box 1168, Suva, Fiji, to whom completed applications (6 copies) should be returned by November 16, 1973. (1401)

QUEEN MARY COLLEGE UNIVERSITY OF LONDON DEPARTMENT OF PHYSICS

Applications are invited for a Postdoctoral Research Associateship to work with Dr. P. E. Clegg on the design, construction and operation of a beam-switching, submillimetre astronomical detector for use on a variety of large telescopes.

Candidates should have a Ph.D. in physics or electronic engineering and experience in infrared photometry or spectroscopy, and preferably also in electronics.

Appointment will be initially for one year, to begin as soon as possible. Salary within range £2,388 to £3,048 per annum, plus £162 London Allowance.

Applications (giving age, qualifications, experience, and names and addresses of two referees) to the Registrar (N), Queen Mary College, Mile End Road, London E1 4NS, as soon as possible. (1402)

JUNIOR TECHNICIAN REQUIRED IN THE Department of Medicine to assist with research. Salary according to age and qualifications.—Apply in writing to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. D.M.1. (1390)

New Influenza Vaccines

Virologist

from £3000

This is an opportunity for a graduate with good experience of virology or vaccine work to play a prominent role in a project concerned with new influenza vaccine research.

The scope of the work spans a wide range of activities from pure research to vaccine development, including the preparation and assay of new virus strains, and the development of new techniques for the culture, purification, concentration and preservation of viruses. To help him in this, he will have two people reporting to him. The work will also involve interdisciplinary cooperation with clinical researchers, production staff and other research and development teams.

The man (or woman) we seek for this key appointment will be aged up to about 35, and will have good research experience in virology or bacterial vaccine work. He should have an applied interest in viruses *per se*, rather than an academic interest in viruses as a research tool.

Particularly advantageous would be familiarity with vaccine work, experience of handling viral cultures on a development scale, practical expertise in biophysical techniques used for purification and preservation, and/or experience of animal experimentation.

Our client is a large and well-known company with extensive interests in chemotherapy and the life sciences, and the position has arisen due to the recent promotion within the Company of the senior scientist previously involved in these studies.

Starting salary for this appointment is likely to be at least £3000, and substantially higher for a particularly suitable candidate. Other benefits include a bonus scheme, free life assurance, generous pension scheme, a pleasant geographical location in Southern England in a lowish cost housing area, and extensive financial assistance towards removal and re-establishment costs.

Please write for an application form, or phone if you would like to discuss the position further:

A. E. F. Chandler, M.A., Ph.D., D.I.C., M.I. Biol.,
Talentmark Limited,
King House,
5/11 Westbourne Grove,
London W2 4UA.

(1441)

Talentmark
Biomedical and Scientific Consultants

THE EDINBURGH SCHOOL OF AGRICULTURE RESEARCH ASSISTANT

Applications are invited for a post of Research Assistant to be employed on an investigation of vernalisation of the seedlings of biennial brassica crops and growth at low temperatures. Candidates should have a good honours degree in Botany or Agricultural Botany and will be expected to register for a higher degree.

Salary scale £830 by £40 to £910. F.S.S.U. Further particulars and application form from the Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG. (1410)

UNIVERSITY OF EDINBURGH DEPARTMENT OF PHYSIOLOGY LECTURER

The University Court invites applications for a post of Lecturer in the Department of Physiology from January 1, 1974. Applicants must have a good Honours degree in Physiology or a related subject, and a Ph.D. or equivalent research experience. The salary scale for Lecturers is: £1,929 by £129 to £2,058 by £165 to £4,368 by £180 to £4,548. Membership of F.S.S.U. is required.

Applications (6 copies), including the names of at least two referees, should be submitted not later than November 17, 1973, to the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YJ, from whom further particulars may be obtained. Please quote Reference 1064. (1409)

MEDICAL RESEARCH COUNCIL RHEUMATISM UNIT

CANADIAN RED CROSS MEMORIAL HOSPITAL
TAPLOW, MAIDENHEAD, BERKS

A graduate research assistant (JUNIOR TECHNICAL OFFICER) is required to work in the field of lysosomal physiopathology in arthritis at the above unit. Some previous experience and interest in cellular physiology or biochemistry is desirable.

Applications, with names of two referees, to the

Wellcome

Graduate Scientists

A Chance to Change Direction

The Wellcome Foundation is a rapidly expanding international pharmaceutical organisation.

A vital link between our R & D activities and the world-wide distribution of medical products by the companies of the Wellcome group is the product registration department based at its London headquarters. Most countries of the world require new medical products to be registered for sale before marketing starts and this work is the responsibility of this department. It involves intelligent use of R & D reports and commercial and other information to meet the varied requirements of registration.

We are looking for a graduate chemist, pharmacist or biological scientist, probably aged 25-35, to join the department. This is a chance to move away from pure technical work and gain experience in an interesting and important sphere of this group's international activities.

In addition to an attractive salary the group offer excellent conditions of employment including assistance with relocation expenses where appropriate.

Please write giving brief career details to: Group Personnel Division (PB), The Wellcome Foundation Ltd., 183 Euston Road, London NW1 2BP

(445)

HOECHST PHARMACEUTICALS RESEARCH LIMITED

RADIOLOGICAL AND GENERAL SAFETY OFFICER

We require an experienced science graduate to act as Radiation and Safety Officer for the Hoechst Pharmaceutical Research Centre presently nearing completion at Milton Keynes, Bucks.

The work of the laboratories will include the extensive use of radio isotopes to solve biological research problems.

The person appointed will be responsible for all aspects of laboratory safety both conventional and radiological including dosimetry, radiation measurement and contamination control for a variety of nuclides as well as effluent control for the entire centre.

This is a responsible position in a new organisation and facilities are first class.

Salary is negotiable, according to qualifications and experience, and there are excellent company benefits including annual bonus, contributory pension scheme and free membership of Private Patients Plan.

Please write, with full details of career to date, to:

**Mrs. M. Hannay, Personnel Officer,
Hoechst UK Limited,
Hoechst House, Salisbury Road,
Hounslow, Middx.
Tel: 01-570 7712**

(1363)

AUTOANALYSIS- FOOD INDUSTRY

Heinz, leaders in the convenience sector of the food industry, require a young graduate, preferably with some experience in continuous flow autoanalysis, to carry out development work on foodstuffs analysis by this technique.

The person appointed must have sufficient experience and initiative to perform this task with minimum supervision.

The Heinz Research Centre is situated in a pleasant parkland setting in Hayes, Middlesex, and assistance in relocation can be offered if necessary. Salary, working conditions and fringe benefits are appropriate to a major food company.

Please write in the first instance giving a brief personal and career summary and quoting present salary to:—

**Mr. K. S. Chivers,
Manager—H.O. Personnel Services,
H. J. Heinz Company Ltd.,
Hayes Park, Hayes,
Middlesex UB4 8AL**

(1367)

L'ECOLE POLYTECHNIQUE FEDERALE DE LAUSANNE

met au concours pour son Département d'Electricité un poste de

PROFESSEUR DE MICROELECTRONIQUE A TEMPS PARTIEL

Domaine d'activité: enseignement théorique et expérimental, en particulier sur les techniques de conception et de fabrication de circuits intégrés. Animation d'un laboratoire pour les étudiants. Collaboration avec les professeurs d'autres départements.

Le poste pourra, au besoin, être occupé à plein temps. Il comportera alors la création d'un laboratoire de recherche.

Qualités requises: formation scientifique approfondie, en particulier dans le domaine de la physique appliquée. Expérience pratique de la fabrication de dispositifs à semi-conducteurs, notamment de circuits intégrés. Talent pédagogique reconnu.

Entrée en fonction: à convenir

Les personnes intéressées, de nationalité suisse ou étrangère, sont invitées à demander le dossier relatif à ce poste à la :

DIRECTION DE L'ECOLE POLYTECHNIQUE FEDERALE DE LAUSANNE 33 AV. DE COUR, 1007 LAUSANNE-SUISSE.

(1378)

MICROBIOLOGIST

A Ph.D. Microbiologist with a strong background in genetics and 5-15 years of experience is needed to manage a group of a dozen people involved in Research and Development in the areas of penicillins, cephalosporins and other antimicrobial agents.

Familiarity with mutation techniques, strain development, antibiotic screening and experimental fermentation would be desirable attributes for the position.

WYETH has been a major producer of antibiotics for the past 30 years and is now expanding its Research and Development efforts in this field. The laboratories are located in Chester County, Pa., in the western suburban Philadelphia area.

Please send reasonably detailed résumé to Mr. Charles L. Smith, Research Administrator.

Editorial Assistant for NATURE

A vacancy has arisen for an editorial assistant in the production department of 'Nature'. The assistant will handle scientific manuscripts from the time they are accepted by the journal until they are published.

This involves proof reading and correcting, communication with authors and collaborating with printers. Although a degree is not a necessary qualification, a good background in science is. Typing skills are also essential.

**Write the Editor, Nature
4 Little Essex Street, London, W.C.2.**

(1449)

THE ANIMAL VIRUS RESEARCH INSTITUTE

PIRBRIGHT, WOKING, SURREY

DEPARTMENT OF EXPERIMENTAL
PATHOLOGY

Applications are invited for a post in the above Department. Applicants should have had experience in histological, histochemical and immunohistological procedures to provide support for a small group studying the pathogenesis of vesicular diseases in farm animals. Familiarity with the preparation of specimens for, and the use of, the electron microscope an advantage. The appointment will be in either the S.O. grade (£1,318 to £2,177) or H.S.O. grade (£2,076 to £2,667), depending on qualifications and experience. Minimum qualifications required: degree in scientific subject, I.M.L.T., H.N.C., H.N.D. or equivalent for appointment in S.O. grade; similar qualifications required for appointment in H.S.O. grade with at least five years' appropriate scientific experience since qualifying; applicants with first or second class honours degrees or equivalent should have had at least two years' post-graduate research experience. Superannuation scheme with allowance to offset contributions. House available for suitable married applicant. Further particulars and application forms from Secretary.

(1398)

SOUTHAMPTON UNIVERSITY HOSPITALS

Royal South Hants Hospital

QUALIFIED TECHNICIAN/ RESEARCH ASSISTANT

required to work with Dr. S. Roath on projects in the field of cell culture and fine structure. Salary for Basic Grade Technician £1,440-£2,292 or Graduate Biochemist £1,278-£1,980 as appropriate.

Further information available from Dr. S. Roath.

Tel.: 559122. Ext. 2128.

Applications giving curriculum vitae and naming two referees should be sent to Personnel Officer, Southampton University Hospitals, 119 Tremona Road, Southampton, SO1 6HU.

Tel.: 777222. Ext. 3002. Closing date November 22nd 1973.

(1405)

SCIENCE MUSEUM

ASSISTANT KEEPER —CHEMISTRY COLLECTIONS

... to be responsible for the development, historical research and the preparation of publications for the Chemistry Collections covering the fields of Pure, Analytical and Industrial Chemistry, and Chemical Engineering.

Candidates should normally have a good honours degree or a post-graduate degree or an equivalent qualification in a branch of Chemistry, Chemical Engineering, Pharmacy or the History of Science. Ability to write lucidly on technical subjects essential.

Salary: Assistant Keeper, First Class, £2,924-£4,788; Assistant Keeper, Second Class, £1,642-£2,620. Level of appointment according to age, qualifications and experience. Starting salary may be above the minima. Non-contributory pension scheme.

For full details and an application form (to be returned by 23 November 1973) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone BASINGSTOKE 29222, ext. 500 or LONDON 01-839 1992 (24 hour answering service), quoting G(43)/382/2.

INSTITUTE OF ORTHOPAEDICS

British Postgraduate Medical Federation
University of London

Applications are invited for the post of

BIOCHEMIST (Senior Grade)

in the Department of Biochemistry, Institute of Orthopaedics. The post involves duties in connection with the clinical chemistry service for the Royal National Orthopaedic Hospital and with the laboratory of a Metabolic Unit for the investigation of bone disease. Opportunities for associated research and for studying for a higher qualification. Whitley scale plus London Weighting.

Applications, stating age, qualifications and experience, to Dr. P. G. Walker, Department of Biochemistry, Institute of Orthopaedics, Brockley Hill, Stanmore, Middlesex, from whom further information may be obtained.

(1419)

Department of the Environment
Princes Risborough Laboratory

Analytical Chemist

■ Investigate timber preservation problems ■ Apply routine analytical techniques ■ Adapt and develop research methods.

□ Degree/HNC in Chemistry □ Age under 30 □ Appointment as Scientific Officer (£1318 - £2177) or Higher Scientific Officer (£2076 - £2667). □ Ref: SA/32/HA □ Closing date 23 November 1973.

□ Application forms from Establishments Office, Princes Risborough Laboratory, Princes Risborough, Aylesbury, Bucks. HP17 9PX.

Overseas Development Administration
Centre for Overseas Pest Research, London

Biologist

■ Investigate mode of action of molluscicides in aquatic snails, using scintillation counting and autoradiographic techniques ■ Post tenable until July 1976.

□ 1st/2nd hon's degree □ Experience in methods employed advantageous □ Age under 30 □ Appointment as Higher Scientific Officer (£2251 - £2842) or Scientific Officer (£1493 - £2352) □ Ref: SA/6/JA □ Closing date 23 November 1973.

□ Application forms from Administrative Secretary, Centre for Overseas Pest Research, College House, Wrights Lane, London W8 5SJ.

Overseas Development Administration
Tropical Products Institute, London SW1

Food Biochemist

■ Join multidisciplinary team studying scientific problems in processing primary products ■ Develop new food products in laboratory ■ Independent work in developing countries possible.

□ 1st/2nd hon's degree □ Relevant experience in food processing, including dehydration □ Age under 27 □ Appointment as Scientific Officer (£1493 - £2352) □ Ref: SA/9/JD □ Closing date 23 November 1973.

□ Application forms from Administrative Secretary, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB.

(1444)

INSTITUTE OF PSYCHIATRY DEPARTMENT OF NEUROLOGY POST-DOCTORAL RESEARCH WORKER

Applications are invited from doctorates in biochemistry/pharmacology for the above post in the Section of Biochemistry of the Department of Neurology. The successful applicant will work on the biochemistry of cerebral amines in relation to basal ganglia disease, and there will be the opportunity to pursue their own research interests. Salary scale £1,926 to £2,241, renewable annually up to 3 years. Closing date November 30.

Applications in writing (quoting Reference PJ/N), together with a curriculum vitae, should be sent to the Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF, from whom further details may be obtained.

Applicants who wish to visit the unit may do so by prior arrangement. Telephone 01-703 5411, Ext. 245. (1359)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON) DENMARK HILL, LONDON SE5 8RX

Applications are invited for a newly established post of LECTURER (non-medical) in Immunology. Commencing salary in the range £1,929 to £4,548 plus £162 London Allowance, according to age, qualifications and experience.

Applications, in writing, not later than November 19, 1973, to the Secretary of the Medical School (N), from whom further particulars may be obtained. (1362)

RIVERINA COLLEGE OF ADVANCED EDUCATION

Applications are invited for appointment to the following position:

GEOGRAPHER

A general human Geographer is required preferably in the field of population/urban geography.

The appointee would be expected to lead a small group of geographers within the School of Applied Science.

Salary: Lecturer, \$A8,698 to \$A11,982; Senior Lecturer, \$A12,268 to \$A14,308.

Substantial experience in university teaching is essential for appointment at Senior Lecturer level.

Application forms and further information may be obtained from the Bursar, P.O. Box 588, Wagga Wagga, N.S.W. 2650 (phone 25 1026, ext. 7). (1372)

UNIVERSITY OF LONDON READERSHIP IN PHARMACOLOGY AT THE SCHOOL OF PHARMACY

The Senate invite applications for the above Readership from candidates with experience in teaching and research in pharmacology. Salary scale £4,368 to £5,496 a year plus £162 London Allowance.

Applications (10 copies) must be received not later than December 5, 1973, by the Academic Registrar (N), University of London, Senate House, London WC1E 7HU, from whom further particulars may be obtained. (1400)

BIOLOGIST

Applications are invited for a full-time opening in the Cell Biology Division for a well-trained Ph.D. interested in committing his/her efforts to developing organ culture systems to investigate the differentiation and altered differentiation of epithelial tissues in response to vitamin A, vitamin A analogues, and carcinogens.

Should have training and background in organ/tissue culture, a good basic biological training, and be acceptably knowledgeable in biochemistry. A recent Ph.D. or one with one to two years' post-doctoral training would be acceptable.

Please send recent curriculum vitae to:

Personnel Office
Southern Research Institute
2000 Ninth Avenue South,
Birmingham, Alabama 35205, U.S.A.

An Equal Opportunity Employer M/F.

(1389)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (UNIVERSITY OF LONDON)

Applications are invited from post-doctoral BIOCHEMISTS experienced in electrophoresis or ENTOMOLOGISTS interested in insecticide resistance in aphids to work with Dr. R. J. Berry on the biochemical detection and maintenance of insecticide resistance in aphids. Salary in the range £1,929 to £2,200, plus F.S.S.U. Benefits. It is hoped to make an appointment as soon as possible, and applications should be submitted before November 21 to Dr. R. J. Berry, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP. (1412)

KINGSTON POLYTECHNIC GRADUATE RESEARCH ASSISTANT

(Salary: £1,427-£1,537)

Honours graduate required to investigate the degradation of plastics by hot water. The project is supervised by Dr. G. Pritchard in the School of Chemical Science and Technology. Candidates should have the capacity to work for a higher degree and be interested in instrumental methods of materials examination.

Apply for forms and particulars as soon as possible to the Appointments Officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE, quoting Ref. GPI. (1414)

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS. AL5 2JQ

BIOLOGIST required for Entomology Department for work on the pathology of insects of agricultural importance. Minimum qualifications: pass degree, H.N.C. or equivalent qualification in biological subjects.

Appointment in grade of Scientific Officer; starting salary £1,318 to £1,590 (depending on qualification and experience) on scale to £2,177. Superannuation with allowance to off-set contributions.

Applications, naming two referees and quoting Reference 2032, to the Secretary by November 30, 1973. (1415)

UNIVERSITY OF AUCKLAND NEW ZEALAND

SCHOOL OF MEDICINE

LECTURESHIP IN HAEMATOLOGY

Applications are invited for the above-mentioned post from candidates holding a medical qualification registrable in New Zealand, together with a recognised postgraduate qualification in either pathology or medicine (for example, F.R.C.P.A., M.R.C.Path., M.R.A.C.P., M.R.C.P.). It is envisaged that the successful applicant will have or will develop a special interest in a particular field of haematology.

Commencing salary will be established in accordance with qualifications and experience. The present salary scale for a medically qualified Lecturer is \$NZ8,931-\$NZ10,551 (bar)-\$NZ12,762 per annum. Lecturers appointed above the bar may be paid an allowance of up to five per cent for clinical responsibilities.

Conditions of appointment, superannuation details, further particulars and application procedure available from the Association of Commonwealth Universities (Appis), 36 Gordon Square, London WC1H 0PF.

Applications close on November 26, 1973.

(1446)

WESTFIELD COLLEGE
(UNIVERSITY OF LONDON)

ELECTRON MICROSCOPE UNIT

requires a **TECHNICIAN GRADE 5** to take charge of the day-to-day running of the Electron Microscope suite and also to take an active part in training Postgraduates in Electron Micrography. The salary will be on the scale £2,007 to £2,382 plus London Allowance per annum. Applicants should hold an I.S.T. diploma in Electron Micrography and be able to use the AG1.801B microscope. Applicants without this qualification but willing to undergo training will also be considered but will be appointed on a lower grade.

Applications, giving full details and the names of two referees, should be sent to the Personnel Officer (N), Westfield College, Kidderpore Avenue, Hampstead, London NW3 7ST, by November 20, 1973. (1451)

**UNIVERSITY OF
WESTERN AUSTRALIA
PERTH**

MATHEMATICS

Applications for appointment as **SENIOR TUTOR** in the Department of Mathematics are invited from persons interested in any area of pure mathematics, applied mathematics, mathematical statistics or mathematical aspects of computation, and who expect to be available to assume duty before March 1974. Candidates should possess an Honours degree or the equivalent, but applications from students who expect to obtain such a qualification before taking up appointment will be considered. The salary range is: \$A7,270-\$A8,698 per annum. Benefits include superannuation similar to F.S.S.U., fares to Perth for appointee and dependent family, removal allowance, long service/study leave, and housing loan scheme. Further information is available from the Chairman of the Department, Professor J. J. Mahony, in the University.

Applications in duplicate, stating full personal particulars, qualifications and experience, should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009, by 24 November 1973. Candidates should request three referees to write immediately to the Staffing Officer. (1447)

MALE GRADUATE (OR H.N.C.) BIOLOGIST required to join a team working in respiratory physiology and inhalation toxicology. Studies are being made into the effects on Primates and Rodents of exposure to cigarette smoke, air pollutants, and therapeutic aerosols. Salary range £1,400-£2,800 depending upon experience.—Application form from: John Halliday, Personnel Officer, Huntingdon Research Centre, Huntingdon PE18 6ES, quoting Reference 279. (1448)

SURREY EDUCATION COMMITTEE

EWELL COUNTY TECHNICAL COLLEGE
Reigate Road, Ewell

DEPARTMENT OF BIOLOGICAL SCIENCES

Required January 1974:

LECTURER I OR II IN PLANT PATHOLOGY to teach up to M.I.Biol. level (Honours degree equivalent).

Candidates should have a 1st degree in an appropriate Biological subject and preferably a higher degree in Plant Pathology. Industrial and/or teaching experience also an advantage.

The Department encourages research either independent of or under the guidance of the Research Director.

Salary: Lecturer I, £1,660 to £2,685 per annum (£2,847 per annum for good Honours graduate); Lecturer II, £2,515 to £3,243 per annum. £118 per annum London Allowance payable.

Generous relocation expenses and assistance with house purchase in approved cases.

Stamped, addressed foolscap envelope, please, for further particulars and application form from the Vice Principal; applications to be returned within 10 days. (1417)

UNIVERSITY OF LEICESTER

DEPARTMENT OF PHYSIOLOGY

LECTURER

Applications are invited for the post of **LECTURER** in the Department of Physiology (Head of Department, Professor R. Whitam, F.R.S.). An interest in teaching medical students is essential, and possession of a medical qualification desirable, but other suitably qualified applicants will be seriously considered. There are excellent research facilities.

Initial salary, dependent on qualifications and experience, within the scale £1,929 to £4,548 a year, with F.S.S.U. membership.

Further particulars from the Registrar, to whom applications should be sent by December 11. (1422)

**Imperial
Chemical
Industries
Limited**

**Industrial Hygiene
Research Laboratories**

Research Assistants

These Laboratories provide central advisory and experimental toxicological services to the Company. As well as evaluating the safety of industrial chemicals, food additives and pesticides, emphasis is placed upon improving and assessing methods for studying the biological effect of chemicals and upon understanding mechanisms of toxicity. Good experimental facilities are available and extensions are planned.

There are a number of interesting positions for men and women who have studied biology to a variety of academic levels (CSE to B.Sc.) and who would like a career in biological research work. Opportunities for further study can be given. Previous laboratory experience would be an advantage.

If you are interested in learning more about these vacancies, please contact:

Tel: Alderley Edge 2711 ext 156

(1442)

**UNIVERSITY OF KHARTOUM
SUDAN**

Applications are invited for (a) **SENIOR LECTURESHIP** or (b) **LECTURESHIP IN VETERINARY SURGERY IN DEPARTMENT OF CLINICAL STUDIES** in Faculty of Veterinary Science. Applicants should possess a Ph.D. or equivalent in veterinary surgery and at least 2 years' teaching experience in veterinary surgery at university level. Appointee will be expected to teach veterinary surgery, including anaesthesia, to final and sub-final year students, do research in the Department, supervise postgraduate students for higher degrees, and participate in clinical and surgical work. Salary scales: Senior Lecturer £52,400 to £52,800 per annum; Lecturer £51,500 to £52,300 per annum (£1 sterling = £50.85). The British Government may supplement salary in range £1,300 to £1,600 per annum (sterling) for married appointee or £800 to £900 per annum (sterling) for single appointee (normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; various allowances; superannuation scheme; annual overseas leave.

Detailed applications (6 copies), including a curriculum vitae and naming 3 referees, should be sent not later than November 29, 1973, to the Personnel Secretary, University of Khartoum, P.O. Box 321, Khartoum, Sudan. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (1361)

JUNIOR TECHNICIAN

required by the Medical Research Council Unit and University Department of Clinical Pharmacology, Radcliffe Infirmary, Oxford. The work will be biochemical and pharmacological with clinical application. No previous experience is required, but the successful applicant will be expected to train for higher qualifications as a Laboratory Technician. Applicants should have at least 4 'O' levels, including English language and 2 science subjects, of which 1 should be mathematics. Salary will be within the scale £708 to £1,395, depending upon age and qualifications.

Applications should be sent to Professor D. G. Grahame-Smith. (1383)

THE R.S.P.B. REQUIRES A RESEARCH BIOLOGIST to investigate large-scale bird mortality and monitor seabird colonies. The work includes organising surveys of beached birds and of colonies of auks and terns. There will be opportunities for field research. Work is based at R.S.P.B. Headquarters, Sandy, and there is regular liaison with other organisations. Applicants should have university degree or equivalent and be competent ornithologists. Knowledge of seabirds, statistics or avian physiology as well as lecturing experience are an advantage. Salary in the range £1,450 by £60 to £1,810 per annum.—For further details and application form send s.a.e. to Mrs. Angela Legge, R.S.P.B., The Lodge, Sandy, Beds. SG19 2DL. (1386)

Institute of Aviation Medicine, Farnborough

Biophysicist

up to £4,575

To join an inter-disciplinary team studying the effects of high energy light on vision, and to be responsible for the optical and electronic aspects of physiological and behavioural studies on man and animals in this field.

Candidates should have a good honours degree in Biophysics or other relevant subject and must have had considerable research experience at a responsible level on lasers preferably with special reference to the biological effects of laser radiation.

Starting salary within the scale £3,472-£4,575 (Principal Scientific Officer grade) according to qualifications and experience with prospects of promotion. The appointment may be permanent and pensionable or, with the present employer's agreement, on secondment terms.

For full details and an application form (to be returned by 26 November 1973), write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke 29222, extension 500, or London 01-839 1992 (24-hour answering service). Please quote SJ8445/2.

(1443)

Ministry of Defence

South African Atomic Energy Board

PELINDABA

Plasma Physicists

A programme of research on laser-heated plasmas in a magnetic field is being undertaken with a view to future thermo-nuclear energy possibilities.

Applications are invited from persons with a Ph.D. degree in Physics who are interested in doing experimental or theoretical work in this field. Preference will be given to applicants with experience of plasma and laser physics. The commencing salary will be determined according to qualifications and experience.

Fringe benefits include: Medical Benefit Scheme, Assisted Housing loan scheme, housing subsidy scheme, Pension and Group Insurance Scheme, Annual Leave Bonus, ample leave privileges and free transport between Pretoria and the Board's site. A person appointed from overseas will receive financial assistance in regard to travelling expenses and the cost of transporting his furniture and effects including a motor car. He is required to make use of all assistance given by the South African Department of Immigration, the amount received from the said Department will be deducted from the financial assistance offered by the Board. He is also required to serve the Board for two years in consideration of the financial assistance received. A non-South African appointee must undertake to apply for South African Citizenship as soon as he qualifies therefor.

Written applications, giving full details of qualifications, experience, employer and salary, etc. should be addressed to:

South African Embassy, Office of the Scientific Counsellor, Chichester House, 278 High Holborn, LONDON WC1V 7HE (Telephone: 01-242 9641).

(1416)

UNIVERSITY OF NEW SOUTH WALES SCHOOL OF CHEMISTRY LECTURER

In the field of analytical chemistry for duties associated with undergraduate and postgraduate courses. High academic qualifications required, together with appropriate postgraduate experience in analytical chemistry and tertiary level teaching experience.

Salary: \$A8,698 range \$A11,982 per annum. Commencing salary according to qualifications and experience.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on 14 December 1973. (1424)

CHELSEA COLLEGE UNIVERSITY OF LONDON

TECHNICIAN (GRADE 3) required in the Analytical Laboratories of the Chemistry Department. Candidates should have a good basic university technical training, experience in the use of spectrophotometers, tools, etc., and be able to do simple glass blowing. Salary scale £1,825 to £2,095 per annum (including London Allowance).

Application forms from the Superintendent of Laboratories (N), Department of Chemistry, Chelsea College, Manresa Road, London SW3 6LX. (1428)

THE UNIVERSITY OF ADELAIDE

Applications are invited for the following appointments:

LECTURER IN BOTANY from beginning of 1974, to teach at both undergraduate and postgraduate levels in ecology, higher degree required. Field should be relevant to current environmental problems and might include plant ecology, general ecology (provided interests embrace plants) or related topics such as phytoplankton and marine productivity or physiology of plants under stress. (15.12.73.)

TEACHING FELLOW IN ORGANIC CHEMISTRY for 1974 from candidates with Ph.D. degrees; to be responsible for practical courses including course innovations and to undertake research with existing research groups, which enjoy modern facilities of high standard. (7.12.73.)

Salary scales: Lecturer \$A8,698 by 470(1) by 469(6) to 11,982; with superannuation on the F.S.S.U. basis; Teaching Fellow \$A7,270 by 286(3) by 285(2) to 8,698; a non-superannuated and non-tenured appointment.

Further particulars about these posts and the conditions of appointment and other information sought will be supplied on request to the Registrar of the University, or to the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications should be sent in duplicate and giving the information listed in the statement that will be supplied, to the Registrar, the University of Adelaide, North Terrace, Adelaide, South Australia 5001. (1427)

UNIVERSITY OF RHODESIA

FACULTY OF SCIENCE

LECTURESHP IN ANIMAL SCIENCE

Applications are invited for the post of Senior Lecturer or Lecturer in Animal Science in the Department of Agriculture. Candidates should have at least an honours degree in agricultural science together with relevant research experience and a knowledge of animal production. A special knowledge of either animal physiology or livestock improvement is essential.

Salary Scale (Approx. stg. equiv.): Lecturer Grade II: £2,711 by £133 to £3,110 by £160 to £4,230; Lecturer Grade I: £4,390 by £160 to £5,030; Senior Lecturer: £4,844 by £186 to £6,332.

Family passages and allowance for transport of effects on appointment. Installation loan of up to half of one year's salary if required. Unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia. Sabbatical and triennial visits with travel allowance. Superannuation and medical aid schemes.

Applications (6 copies), quoting Ref. No. UK/29/73 and stating where advertisement seen, and giving full personal particulars (including full names, place and date of birth etc.), qualifications, experience and publications, and naming three referees should be submitted by 17 November 1973, to the Assistant Registrar (Science), University of Rhodesia, P.O. Box MP 167, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars can be obtained. Additional copy to the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, from whom further

ZOOLOGICAL SOCIETY OF LONDON

ASSISTANT EDUCATION OFFICER

A graduate in Zoology is required to lecture and demonstrate at London Zoo and, during the summer, Whipsnade Zoo to pupils of varying abilities ranging in age between 8 and 18 plus years.

Previous teaching experience would be an advantage but is not essential. An interest in photography and the production of tape/slide materials would be an added recommendation.

Other duties involved are concerned with the meetings and magazine of the Young Zoologists' Club, in information work, and in assisting with administrative work.

The salary is Burnham Scale 2 plus London weighting. Annual leave is 18 working days.

The successful candidate should be prepared to take up the post in the new year. Detailed applications in writing should be sent to:

**The Establishment Officer,
Zoological Society of London,
Regent's Park, London NW1 4RY.**

(1454)

NEWCASTLE UPON TYNE POLYTECHNIC

Ellison Building, Ellison Place, Newcastle upon Tyne NE1 8ST

Required as soon as possible

Department of Materials Science

RESEARCH ASSISTANTS

are required for research projects financed by the Science Research Council and the Ministry of Health. One post is for a study of the products of burning plastics and the other is for applications of plastics reinforced with carbon and other fibres.

Suitable graduates may be permitted to register for a higher degree.

Salary scale: Research Assistant £1,200 to £1,500.

Further information may be obtained from Dr. T. R. Manley at the above address.

(1406)

MONASH UNIVERSITY MELBOURNE, AUSTRALIA

DEPARTMENT OF EARTH SCIENCES

SENIOR LECTURER/LECTURER

Applications are invited for the position of Lecturer/Senior Lecturer in the Department of Earth Sciences in the Faculty of Science. Preference will be given to applicants with interests in hard-rock geology (including igneous, metamorphic and sulphide petrology, experimental petrology and structural geology). The department is developing well equipped experimental, analytical and electron microscopy laboratories and it is intended that the successful applicant should have interests compatible with these lines of research.

Salary scale: Senior Lecturer: \$A12,268 to \$A14,308 per annum. Lecturer: \$A8,698 to \$A11,982 per annum, with superannuation based on an endowment assurance scheme, the employee and employer contributing 5% and 10% respectively.

Benefits: Travelling expenses for appointee and family; removal allowance; repatriation after three years' appointment if desired; temporary housing for an initial period; availability of loans for home purchase; study leave entitlement accumulates at the rate of one month's leave for each six months' service up to six years, with provision for financial assistance.

Further general information and details of application procedures are available from the Academic Registrar, Monash University, Wellington Road, Clayton, Victoria 3168, Australia, or the Secretary-General, Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF. Enquiries about the department should be sent to the Chairman, Professor B. E. Hobbs, in the University.

Closing Date: December 1, 1973.

The University reserves the right to make no appointment or to appoint by invitation. (1433)

ROYAL POSTGRADUATE MEDICAL SCHOOL

GRADUATE TECHNICAL OFFICER (Microbiology) required to work in the Routine Diagnostic Bacteriology Laboratory. Applicants should have had previous experience in a clinical laboratory. Salary according to qualifications and experience but not less than £1,800 per annum.

Applications to the Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, W12 0HS, quoting reference 5/125/N. (1434)

Have you ever considered becoming a MEDICAL REPRESENTATIVE?

CAT is the consultancy specialising exclusively in the medical and pharmaceutical industries. We are now looking for men to fill key positions in both the hospital and G.P. fields in several parts of the country.

If you are 22-30 and looking for a new and worthwhile development in your career which can offer you a high immediate salary ring 01-794 6298 or write to:

Career Appointments and Training, 36 Grosvenor Street, Mayfair, London W1X 9FG. (1421)

UNIVERSITY OF NEW SOUTH WALES

WOLLONGONG UNIVERSITY COLLEGE
to become the
UNIVERSITY OF WOLLONGONG
on January 1 1975

PROFESSOR OF COMPUTING SCIENCE

Applications are invited for appointment to a second chair in the Department of Mathematics. Applicants should have particular interests in design and implementation of computer software. The professor will supervise and participate in teaching and examining undergraduate and postgraduate students in the Department and engage in and promote research and advanced study in the field of his chair. In addition he will develop new options within the Department of Mathematics for science and engineering students at both undergraduate and postgraduate levels.

Salary: \$A19,102 per annum. Subject to the consent of the University Council, professors may undertake a limited amount of higher consultative work. The University reserves the right to fill any chair by invitation.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on November 23, 1973. (1437)

UNIVERSITY OF HONG KONG LECTURES/ASSISTANT LECTURES/ASSISTANT ENGINEERING

Applications are invited for posts of Lecturer/Assistant Lecturer in Mechanical Engineering. Applicants should have some years of experience in industry. Preference will be given to persons with expertise in any of the following fields:

- Mechanics of machines and vibration.
- Strength of materials and mechanical properties.
- Environmental engineering.
 - Air conditioning and solar energy applications.
 - Desalination technology.

All applicants will be expected to take part in the teaching of part I subjects and to participate in a postgraduate teaching programme planned to start in October 1974. A graduate in chemical engineering could be an appropriate candidate to develop studies in desalination, besides teaching fluid mechanics and heat transfer.

Annual salaries (superannuable) are Lecturer: HK\$40,800 by 2,760 to 46,320 BAR 49,080 by 2,760 to 68,400; Assistant Lecturer: HK\$29,760 by 2,760 to 38,040. At the time of issue the rate of exchange is £1=HK\$12.00 approximately.

Starting salary will depend on qualifications and experience. Salaries for female appointees below HK\$62,880 are slightly lower than given above; equalization of male and female salary scales will be achieved by April 1, 1975.

Further particulars and application forms may be obtained from the Secretary-General, Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF, or the Secretary to the Council, University of Hong Kong.

Closing date for applications is December 5, 1973. (1436)

QUEENSLAND INSTITUTE OF TECHNOLOGY BRISBANE, AUSTRALIA SCHOOL OF APPLIED SCIENCE

QUOTE: V. 152.73

Within the Queensland Institute of Technology the School of Applied Science offers degree courses in Applied Chemistry, Biology, Computing Science, Mathematics, Medical Technology and Physics. In addition, postgraduate diplomas and master's degree courses in specific vocational areas are being planned for implementation in the near future. A number of undergraduate diploma courses are also organised within the School.

Applications are invited for the following academic appointments:

Department of Biology and Environmental Science
**SENIOR LECTURER IN FRESH WATER
PLANT PRODUCTIVITY**

Department of Chemistry
SENIOR TUTOR IN ORGANIC CHEMISTRY
Department of Mathematics and Computer Science
LECTURER IN FINANCIAL MATHEMATICS

SENIOR TUTORS (4 POSITIONS)

Department of Paramedical Studies

LECTURER IN OPTOMETRY

Department of Physics

SENIOR LECTURER/LECTURER

Salary Ranges:

Salary ranges for lecturing staff are normal Australian University rates.

Senior Lecturer \$12,268 to \$14,308 per annum.

Lecturer I \$8,698 to \$11,982.

Lecturer II \$7,165 to \$9,674.

Senior Tutor \$6,969 to \$7,855.

Further particulars and details of positions may be obtained from the Registrar, Queensland Institute of Technology, P.O. Box 246, North Quay, Brisbane, 4000.

Applications containing full personal particulars, details of qualifications and experience, and the names and addresses of two referees should be forwarded to the Registrar, at the above address. Closing date for receipt of applications is December 3, 1973. (1420)

NEW ZEALAND UNIVERSITY OF CANTERBURY Christchurch SENIOR LECTURER OR LECTURER IN ZOOLOGY (ANIMAL PHYSIOLOGY)

Applications are invited for the above-mentioned position. Experience and research interest in respiration, excitable tissues and/or sensory physiology are desirable.

The salary for Lecturers is on a scale from \$NZ6,575 to \$8,343 per annum, and for Senior Lecturers \$NZ8,489 to \$9,963 (bar) \$10,259 to \$10,846 per annum.

Particulars including information on travel and removal allowances, study leave, housing and superannuation may be obtained from the Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF.

Applications close on November 30, 1973. (1435)

THE OPEN UNIVERSITY

Science Faculty

Technician Grade 4 in Chemistry

Applications are invited for the above post to be taken up as soon as possible.

Duties include the preparation of home experiments, summer school experiments, T.V. demonstrations and in particular assisting with research within the discipline.

Salary within the scale: £1,848-£2,163 per annum.

Further particulars may be obtained from The Acting Personnel Manager (C2), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL.

Applications should be returned as soon as possible.

(1450)

UNIVERSITY OF
NEW SOUTH WALES
WOLLONGONG UNIVERSITY COLLEGE
to become the
UNIVERSITY OF WOLLONGONG
on January 1, 1975

PROFESSOR OF BIOLOGY

Applications are invited for appointment to the above-mentioned chair in the Division of Biological and Chemical Science. Applicants should have interests in all branches of biology but the University is particularly interested in attracting candidates with a background in ecology or physiology. The appointee will contribute to the development of a complete biological programme and will supervise and participate in teaching and examining undergraduate and postgraduate students and engage in and promote research and advanced study in the field of his chair.

Salary: \$A19,102 per annum. Subject to the consent of the University Council, professors may undertake a limited amount of higher consultative work. The University reserves the right to fill any chair by invitation.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on November 23, 1973.

(1432)

TECHNICIANS (2) REQUIRED IN BACTERIOLOGY DEPARTMENT for research with group investigating immune defences to bacterial infections. Salary according to age, experience and qualifications within scale £1,440/£2,292 per annum plus £126 per annum L.W.—Apply, The Secretary, St. Mary's Hospital Medical School, Paddington, W2 1PG.

(1455)

Scottish National Blood Transfusion Association NON-MEDICAL SCIENCE GRADUATE (PRINCIPAL GRADE) IN THE REGIONAL TRANSFUSION CENTRE, LAW HOSPITAL

Applications are invited for a scientist to head a small team of graduates in a progressive regional transfusion centre. The post is suitable for a graduate in biochemistry or a biological discipline; previous experience in blood transfusion is not essential. Possession of a higher degree is desirable.

In addition to research there are opportunities for teaching at undergraduate and postgraduate level. The laboratories are modern and in pleasant surroundings.

The post is superannuable (N.H.S. Superannuation Scheme).

Further details may be obtained from the under-mentioned to whom applications, with names and addresses of two referees, should be sent by not later than November 23, 1973.

Neil A. Milne, WS, Secretary,
Scottish National Blood Transfusion
Association,
5 St. Colme Street,
Edinburgh EH3 6AE.

(1456)

UNIVERSITY OF RHODESIA

FACULTY OF ARTS

Applications are invited for:

SENIOR LECTURESHIPS/LECTURESHIPS IN GEOGRAPHY (Two Vacancies): Applicants should indicate the full range of their interests and abilities as well as their special field. For one post, preference may be given to applicants with qualifications in biogeography (preferably with wide interests in vegetation studies) and, for the second, in the general field of human geography, but applications from any well-qualified persons are invited. Ability to teach a course in the regional geography of an area other than N.W. Europe and Africa may be a secondary recommendation.

Salary scales (approx. stg. equiv.): Senior Lecturer: £4,844 by £186 to £6,332; Lecturer Grade I: £4,391 by £160 to £5,031; Lecturer Grade II: £2,711 by £133 to £3,110 by £160 to £4,230.

Family passages and allowance for transport of effects on appointment. Assistance with accommodation for up to three years for persons recruited from outside Rhodesia. Sabbatical and triennial visits with travel allowance. Superannuation and medical aid scheme.

Applications: (6 copies) giving full personal particulars (including full names, place and date of birth, etc.), qualifications, experience and publications and naming three referees, should be submitted by November 30, 1973, to the Registrar, University of Rhodesia, P.O. Box MP 167, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars may be obtained. Additional copy to the Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF, from whom further particulars may also be obtained.

(1431)

BEDFORD COLLEGE

(UNIVERSITY OF LONDON)

Department of Physics

Applications are invited from suitably qualified graduates in mathematics, physics, or chemistry for the post of

RESEARCH ASSISTANT/PROGRAMMER

under a 3-year grant from the Science Research Council. The appointee will be working under the direction of Dr. M. R. Hoare on the statistical mechanics and microcrystallography of small atomic and molecular clusters. Excellent computing facilities are available. Appointment for 1 year in the first instance from 1 January, 1974, or an earlier agreed date.

Salary within the range £1,572 by increments to £1,923 per annum.

Application forms and further particulars may be obtained from the Assistant Secretary (Personnel) (N), Bedford College, Regent's Park, London NW1 4NS. Telephone (01) 486 4400, Ext. 313.

(1429)

FELLOWSHIPS AND STUDENTSHIPS

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF CHEMISTRY

Applications are invited for a Postdoctoral Fellowship in Inorganic Chemistry. Interests in organometallic chemistry, nuclear magnetic resonance spectroscopy, high temperature chemistry, high resolution spectroscopy, or mass spectrometry.

Apply, giving a brief curriculum vitae and the names of two referees, to Professor I. R. Beattie, Department of Chemistry, The University, Southampton SO9 5NH, quoting Ref. Na. (1373)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF ELECTRICAL ENGINEERING

RESEARCH FELLOWSHIP

A challenging research post is available for a period of up to three years to work on magnetic-field problems in turbogenerators with superconducting rotors. Suitable candidates will have some industrial experience or a higher degree, a knowledge of electrical machines and electromagnetism, and, above all, enthusiasm for the subject. The initial salary will be up to £2,553, plus annual increments of £165. F.S.S.U. membership is available.

Applications, giving details of age, qualifications and experience, together with the names of two referees, should be sent to the Deputy Secretary's Section (Ext. 2400), The University, Southampton SO9 5NH, not later than November 25, 1973. Please quote Reference Na286/R.

(1374)

ASSISTANTS AND FELLOWSHIPS

available for graduate study in materials science and engineering leading to M.S. and Ph.D. Research areas include mechanical properties, crystal growth, surfaces, corrosion, electronic properties, biomaterials, fuel cells and batteries, phase transformations and materials synthesis and processing.

For information write: Chairman, Department of Materials Science and Engineering, Stanford University, Stanford, California 94305.

(1380)

EDINBURGH CORPORATION

NAPIER COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF MATHEMATICS AND COMPUTING

Applications are invited for a FELLOW-SHIP for a project within the National Development Programme in Computer Assisted Learning. Applicants should be computer scientists with postgraduate experience to Ph.D. level. Experience of algebraic manipulators would be an advantage.

The appointment will be for 16 months in the first instance and the salary will be £2,100 per annum.

Further particulars and application forms from the Principal, Napier College of Science and Technology, Colinton Road, Edinburgh EH10 5DT, to whom they should be returned by November 23, 1973, quoting Reference Number N/231. (1369)

UNIVERSITY OF MELBOURNE

JUNIOR RESEARCH FELLOW IN MARINE BACTERIOLOGY

in the SCHOOL OF MICROBIOLOGY

Applications are invited for this position.

QUALIFICATIONS: The successful applicant should hold a Ph.D., have had research experience in marine or aquatic bacteriology, and be capable of independent research.

DUTIES: The Fisheries and Wildlife Department of the State of Victoria is co-ordinating a Pollution Survey of Port Phillip Bay. The Junior Research Fellow will study the bacterial flora of different representative environments in the Bay, to evaluate the effects of current practices of water management. These results will be co-ordinated by the Fisheries Department with studies of other parameters and used to construct a mathematical model of the Bay. The bacteriological research will be done in the School of Microbiology, and technical assistance will be provided; facilities for field work will be provided through the Fisheries and Wildlife Department.

SALARY: \$A7,556 in the first instance, with annual increments to \$A8,128. Limited assistance is available for travel to Australia for an overseas applicant.

The successful applicant would be required to begin duties in January 1974 and the grant is available for 3 years from that date. Further information can be obtained from Dr. N. F. Millis, School of Microbiology, University of Melbourne, Parkville 3052, Victoria, Australia.

Details of application procedure are available from the Registrar, University of Melbourne, Parkville 3052, Victoria, Australia. Applications, referring to Position No. B/2/73 and including the names of at least two referees, should be addressed to the Registrar and close on December 5, 1973. (1426)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF MEDICAL MICROBIOLOGY

Applications are invited for an M.R.C. POST-DOCTORAL FELLOWSHIP, tenable as soon as possible. The successful candidate would work on the departmental programme of research on the pathogenesis of gonococcal infections. The salary will be in the range for University Lecturers according to qualifications and experience. Further particulars from the Registrar and Secretary to whom applications should be sent by November 23, 1973. Quote Ref. R/87/G. (1438)

ROYAL FREE HOSPITAL

SCHOOL OF MEDICINE

(UNIVERSITY OF LONDON)

JUNIOR RESEARCH FELLOWSHIP

Applications are invited from graduates with an Honours degree in physiology, with some biochemistry, to work in the Department of Physiology in the transfer of substances, particularly folates, across the placenta. The successful applicant will be expected to register for a higher degree. Value of the Fellowship is £1,344 per annum and the appointment will be limited to three calendar years.

Applications and requests for further information should be addressed to Professor C. B. B. Downman, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP. (1403)

POLYTECHNIC OF THE SOUTH BANK

DEPARTMENT OF MATHEMATICS

RESEARCH FELLOW

(Ref. X.23)

Candidates may offer any suitable field of mathematics, computer science, statistics or operational research. They should normally have completed a three-year course of postgraduate training and have shown an aptitude for original and independent research. Fellowships are usually held for a period of two years. Salary £1,984 to £2,239 per annum.

Further particulars and application forms from the Clerk to the Council (Room 538), Polytechnic of the South Bank, Borough Road, London SE1 0AA. Tel. 01-928 8989. (1377)

THE LEVERHULME TRUST

Research Awards 1974

The Leverhulme Trustees, through their Research Awards Advisory Committee, offer:

(i) FELLOWSHIPS AND GRANTS—

To assist senior persons pursuing investigations, particularly those who are prevented by routine duties or any other cause from undertaking or completing a research programme. These awards are not available for persons reading for higher degrees or equivalent awards. No subject of enquiry is excluded from consideration.

The awards are limited to persons educated in the United Kingdom or in any other part of the Commonwealth who are normally resident in the United Kingdom. The duration of the awards does not extend over more than two years or less than three months, and the amount of the award depends on the nature of the work and the circumstances of the case.

The closing date for applications (Form F/2C) is December 1, 1973. The period of award may start from June 1, 1974.

(ii) EMERITUS FELLOWSHIPS—

A limited number of awards to assist persons who have recently retired or who are about to retire from academic positions in universities or institutions of similar status in the United Kingdom and who have an established record of research. They are designed to help in the completion and preparation for publication of the results of such research.

The award attached to the fellowship is to meet incidental costs such as typing, secretarial or research assistance, books, photostats, preparation of plates or blocks, apparatus or equipment, travel and subsistence away from home for essential visits to libraries and other sources of original material. It is not normally intended to provide a personal allowance or a pension supplementation. The fellowships are tenable for one or two years and are not thereafter renewable. The amount of the award depends on the nature and cost of the assistance sought but does not exceed a rate of £2,000 a year.

The closing date for applications (Form F/6C) is December 1, 1973. The period of award will normally date from June 1, 1974.

(iii) FACULTY FELLOWSHIPS IN EUROPEAN STUDIES—

A limited number of awards to strengthen the teaching of European Studies in the universities of this country. These awards are intended to assist established members of the staffs of universities in the United Kingdom to undertake advanced study or research in a European country or countries excluding the British Isles in their particular fields of interest. The fellowships are designed to enable scholars in this country directly to consult their academic colleagues in Europe and to have access to sources of original materials.

The fellow must spend at least six months in Europe normally in not more than two separate periods.

The award attached to the fellowship may be expected to cover the direct costs involved in the fellow's study programme such as subsistence while abroad, travel to and from the European country or countries in which the fellow wishes to study, internal travel within the country or countries and other incidental expenses. The award will not normally provide for salaries or personal allowances. It will vary as to amount to meet the circumstances of each case, but will not normally exceed the rate of £250 a month with a maximum total value of £2,000.

The closing date for applications (Form FF/10C) is December 31, 1973. The period of award may start from June 1, 1974.

(iv) OVERSEAS STUDENTSHIPS—

Up to six studentships for a period of advanced study or research in any subject at an institution of university or university college status in any part of the world other than the United Kingdom, Europe or North America.

At the time of application candidates should be graduates of a United Kingdom university, holders of C.N.A.A. degrees or able to show evidence of equivalent education. They should also have been educated at a school or schools in the United Kingdom or in any other part of the Commonwealth. They must be normally resident in the United Kingdom and under the age of 30 on October 1 in the year of the award.

The value of the studentships is £1,000 per annum. In addition, an amount of £200 will be provided towards outfit and return passages; additional assistance will be available where the cost of the student's return passage exceeds £180 or to meet abnormal requirements connected with the course of study. A further allowance of £25 per month may be paid, at the discretion of the Committee, to a married student when accompanied by his wife.

The awards are tenable for one year or two years if circumstances warrant it. The awards may not normally be held in conjunction with other major awards. Students will be asked on termination of an award to make a short report to the Committee on their experience during the period of study.

Candidates must be available for interview in London late in March; travelling expenses within the United Kingdom will be refunded. Successful candidates will be required to undergo a medical examination before confirmation of their awards.

The closing date for applications (Form O/2C) is January 15, 1974. The period of award will normally date from October 1, 1974.

(v) EUROPEAN STUDENTSHIPS—

Up to eight studentships of £1,200 for one year for advanced study or research in a centre of learning in any European country other than the United Kingdom or Ireland. A further allowance of £25 per month may be paid, at the discretion of the Committee, to a married student when accompanied by his wife.

At the time of application candidates should be graduates of a United Kingdom university, holders of C.N.A.A. degrees or able to show evidence of equivalent education. They should also have been educated at a school or schools in the United Kingdom or in any other part of the Commonwealth. They must be normally resident in the United Kingdom and under the age of 30 on October 1 in the year of the award.

The studentships are tenable only at or in connection with a university, college or similar institution. They are not intended for students of modern languages; otherwise no subject of study will be excluded but preference will be given to candidates who intend to study in subjects normally grouped in the Arts and Social Studies Faculties of universities.

The period of award normally begins on October 1 and students will be required on termination of the award to make a short report to the Committee on their experience during the year of study. The awards may not normally be held in conjunction with another major award.

Candidates must be available for interview in London in the second half of April; travelling expenses within the United Kingdom will be refunded.

The closing date for applications (Form E/2C) is January 15, 1974. The period of award will normally date from October 1, 1974.

The results of applications for all the above awards will be communicated to the candidates in April, 1974. Application forms and further information from The Secretary, Research Awards Advisory Committee, The Leverhulme Trust, 21/23 New Fetter Lane, London EC4A 1NR. Telephone: 01-248 1910.

(1379)

UNIVERSITY OF NEW ENGLAND
ARMIDALE, NEW SOUTH WALES

TEACHING FELLOW IN GEOPHYSICS

Applications are invited from graduates with a degree in Geophysics, Physics, Geology and Mathematics, or Electronic Engineering, for this appointment commencing April 29, 1974. Duties will involve the development and supervision of student practical work, together with research work in the development and field testing of various geophysical instruments.

Salary range: \$A5,740 to \$A7,015 (base plus 5 annual increments).

Assistance is given with travel and removal.

Further information can be obtained from the Secretary-General, Association of Commonwealth Universities (Appis.), 36 Gordon Square, London WC1H 0PF.

Applications close on 28 November 1973.

(1425)

GRANTS & SCHOLARSHIPS

£600 POST-GRADUATE GRANTS

MSc Dairy Science at Reading University

The Dairy Industry offers a limited number of special grants worth £600, plus all fees, for the one-year MSc course in Dairy Science at Reading University.

This post-graduate course is available to holders of first degrees or equivalent qualification in pure or applied science (including agriculture).

The awards are designed for those students who show outstanding potential for responsible scientific, technical and managerial positions in the processing and manufacturing sides of the Dairy Industry.

The MSc qualification could also lead to lectureships in dairy science and technology.

Applicants must be resident in the United Kingdom, and intent upon taking up employment in the United Kingdom Dairy Industry on completion of the course. All applications for the 1974 award must reach us by 31 January 1974.

For full details, please write to, or telephone:

Mrs Jacqueline Gray, Department 66,
The Dairy Industry Training
& Education Committee,
The Joint Committee, Giggs Hill Green,
Thames Ditton, Surrey KT7 0EL
Tel: 01-398 4101, Ext. 436.

(1368)

FRENCH GOVERNMENT SCHOLARSHIPS FOR further study and postgraduate research in France in Pure and Applied Science, Technology, Medicine, Social Sciences, Economics, Geography and Agriculture are offered for the academic year 1974-1975. Candidates, who must be United Kingdom citizens, should be university graduates or have equivalent qualifications. Closing date: December 31, 1973. —Details from Scientific Department, French Embassy, 41 Parkside, Knightsbridge, London SW1X 7JP. Citizens of the Commonwealth and of other countries should apply to French Embassies in their respective countries. (1309)

UNIVERSITY OF STRATHCLYDE

Department of Biochemistry

M.R.C. SCHOLARSHIP

A scholarship is available for up to three years, in the Department of Biochemistry, for work on ornithine decarboxylase in Reproductive Tissues. The scholar, who should possess a First or Upper Second Class Honours Degree in Biochemistry or cognate discipline, would be registrable for a Higher Degree, and would work closely in conjunction with the M.R.C. research group in Biochemistry of Reproduction, established within the Department.

Applications to Professor P. J. Heald, Department of Biochemistry, Royal College Building, University of Strathclyde, 204 George Street, Glasgow G1 1XW, from whom further information can be obtained. (1453)

POSTDOCTORAL FELLOWSHIP
for TEXTURE RESEARCH

Applications are invited for a post of Research Fellow to work on texture research. The research would involve the study of applications of crystallite orientation distribution function analysis in the study of texture, metal deformation and formability. The appointment is for a period of three years with a salary depending on age in the range £1,929 (age 24) to £2,388 (age 27) with provision for annual increments. Previous experience in texture research would be an advantage but is not necessary. Applications, including a brief curriculum vitae, research experience and the names and addresses of two referees, should be sent to Dr. G. J. Davies, Department of Metallurgy and Materials Science, University of Cambridge, Pembroke Street, Cambridge CB2 3QZ. (1440)

UNIVERSITY OF STRATHCLYDE

Department of Pharmaceutical Technology

RESEARCH STUDENTSHIP

An opportunity arises for a young graduate with suitable qualifications to undertake research for three years leading to Ph.D. The field of study may be chosen from one of the principal research activities of the department, viz. cell studies, bioavailability of drugs, microbiological pharmacy, effects of drugs on enzymes.

Financial support on S.R.C. (research studentship) scale is available.

Apply in the first instance to Professor W. Anderson, Department of Pharmaceutical Technology, Royal College Building, University of Strathclyde, 204 George Street, Glasgow G1 1XW. (1411)

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

ANNOUNCEMENT

EMBO WORKSHOP
ON PROTOPLASTS OF PLANTS AND FUNGI AS
GENETIC SYSTEMS

The WORKSHOP will be held at the Department of Botany, University of Nottingham, U.K., from July 29 to August 2, 1974. The programme will include some practical work and demonstrations, and discussions on: the development of plant and fungal protoplasts in culture; fusion and heterokaryon formation using plant and fungal protoplasts and aspects of somatic hybridisation; uptake of viruses by plant and fungal protoplasts and aspects of virus infection and transduction; and the general use of plant and fungal protoplasts as genetic systems.

Participation is limited to 40-50 persons. Applications should contain name, age, address, place of work and position held, reasons for wanting to attend the Workshop, and the name of one referee. Applications should be sent by January 1, 1974, to Professor E. C. Cocking, Department of Botany, University of Nottingham, University Park, Nottingham NG7 2RD, U.K. Notification of acceptance will be given early in 1974. All accommodation expenses at Nottingham will be covered by EMBO and a limited amount of travel support will be available for younger workers. (1385)

INSTITUTE OF CONNECTED EDUCATION

offer prizes for research in pure general science. That is, research in interdisciplinary sciences, or if and how all sciences are interconnected. Main object of the Institute is to create and sponsor the acceptance of a course of this nature in schools, colleges and institutes.

For further information please apply in writing to: The Secretary, Institute of Connected Education, 28a Cadogan Place, London SW1X 9RX. (1388)

QUEEN'S UNIVERSITY OF
BELFASTDEPARTMENTS OF
BIOCHEMISTRY AND MEDICINE
POSTDOCTORAL RESEARCH
FELLOWSHIP

Applications are invited for an M.R.C. sponsored Postdoctoral Research Fellowship to collaborate on the chemical and physiological characterisation of polypeptides from gut which have immunoreactive properties of a glucagon. Radioimmunoassays and affinity chromatography on solid-phase antibodies are routinely used in this work.

Applicants should have experience in protein chemistry.

The appointment is for three years, with a salary scale of £1,929—£2,058—£2,223 plus F.S.S.U.

Further particulars, if desired, may be obtained from Personnel Department, The Queen's University of Belfast, Belfast BT7 1NN, where applications should be received by November 19, 1973. (1413)

LECTURES AND COURSES

UNIVERSITY OF BIRMINGHAM
M.Sc. COURSES AND RESEARCH
FACILITIES

Applications are invited for admission to the following one-year M.Sc. courses which may be offered commencing in September/October 1974:

Analytical Chemistry; Applied Genetics; Brewing Science; Clinical Biochemistry; Clinical Psychology (two-year course); Conservation and Utilization of Plant Genetics Resources; General Virology; Immunology; Meteorology and Climatology; Neurocommunications; Radiobiology.

Details of these courses and of the facilities which are available for those students wishing to undertake research leading to the degrees of Ph.D. and M.Sc., together with forms of application for admission, may be obtained from the Assistant Registrar (S), University of Birmingham, P.O. Box 363, Birmingham B15 2TT, quoting PG.7. (1396)

UNIVERSITY OF LONDON: A LECTURE entitled "Crystal Chemistry of Mercury" will be delivered by Professor D. Grdenić (Zagreb) at 6 p.m. on November 13 at Birkbeck College, Department of Chemistry, Malet Street, W.C.1. Admission free, without ticket.—Academic Registrar. (1355)

UNIVERSITY OF LONDON: A LECTURE entitled "Surface Forces, Surface Energy and Adhesion" will be delivered by Dr. David Tabor (Cambridge) at 5 p.m. on November 8 at Birkbeck College (Large Chemistry Lecture Theatre), Malet Street, W.C.1. Admission free, without ticket.—Academic Registrar. (1356)

UNIVERSITY OF LONDON: A LECTURE entitled "Kepler: A Nightmare to Philosophers of Science" will be delivered by Professor Kurt Hübner (Kiel) at 5 p.m. on November 9 at the London School of Economics and Political Science, Houghton Street, Aldwych, W.C.2. Admission free, without ticket.—Academic Registrar. (1357)

LASERS IN
COMBUSTION
RESEARCH

A post-experience course of nine lectures arranged by Professor F. J. Weinberg will be given in the Department of Chemical Engineering and Chemical Technology, Imperial College, London S.W.7, from December 11-14, 1973.

Details from the Registrar. (1366)

When you need to know enzymes Miles can help!

We at the Research Division are big enough to supply your enzyme requirements in kilogram quantities. But we are small enough to handle micrograms for the most sophisticated researcher. Our catalogs, with over 150 enzymes and purity variations, are complete with assay methodology and detailed specifications. Our introduction of ENZITE[®], the first immobilized enzymes, is only one example of our commitment to filling your needs and our continuing two-way dialog with the research community. We cannot catalog the answer to every question so we have people around the world to aid you. If you have a problem or question just call or write to the office nearest you for personalized assistance. We are here because no problem is small enough until it has been solved.

Whatever type of radiochemical product – labelled compound or isotope:

Whatever the specifications you require for your particular application – ultra-high specific activity, low specific activity with high stability, specially high purity or specially positioned labels:

However quickly you need it:

It is reassuring to know that your local distributor can almost certainly supply it immediately – if not directly from his

own stock then by fast air freight from Amersham.

It is even more reassuring to know that when you need technical assistance or advice, no matter where in the world your laboratory is situated a call to your local distributor can not only arrange prompt delivery of exactly the labelled compound you need – it can also mobilize for you the full resources of The Radiochemical Centre, Amersham.

there's The Radiochemical Centre.

Our experienced technical staff are always ready to advise you, in writing or in person – they have already visited customers in more than 40 countries and will travel well over half a million kilometres during next year. They are all working scientists in the laboratories at Amersham, where they maintain a constant familiarity with the products, product applications, and customer problems.

Next time you need a labelled compound, remember that The Radiochemical Centre is as close as your local

distributor. It's all part of the unique service that adds up to real value for money.

We'll gladly send you the name of our distributor in your country, please write.

And our associate companies are always ready to help.

The Radiochemical Centre Limited, Amersham, England.
In the Americas: Amersham/Searle Corp, Illinois 60005. Tel: 312-593-6300.
In W. Germany: Amersham Buchler GmbH & Co, KG, Braunschweig.

The Radiochemical Centre

This is a new P.A.G.E.

Pharmacia Gel Electrophoresis System for polyacrylamide gradient electrophoresis and other P.A.G.E. techniques

The complete system

Full capabilities for the new pore gradient electrophoresis technique, two dimensional studies, gel rod electrophoresis.

Polyacrylamide gradient gels PAA 4/30

Convenient ready-to-use gradient gel slabs give extreme resolution over the whole range 50,000–2 million MW. Self-limiting migration concentrates the zones after separation by molecular size.

Gel electrophoresis apparatus GE-4

4 gel slabs, 12 samples on each, or 16 gel rod capacity. Robust moulded construction with built-in cooling system. Full range of accessories for all applications.

Electrophoresis power supply EPS 500/400

Compact, all solid state. 0–400 mA constant current, 0–500 V constant voltage with automatic cross-over. Maximum effect 60 W. Full personnel and instrument protection. Available 1974.

Gel destainer GD-4

Electrophoretic or diffusion destaining of slabs or rods in a single operation. Twin cells. Active dye removal and solvent circulation. Results can be inspected at any time.

Destainer power supply DPS

Compact, reliable, all solid state. Push-button selected constant voltages 12, 24, or 36 V. Timer controls electrophoretic destaining up to 90 minutes.

Find out more about the Pharmacia Gel Electrophoresis System from your usual supplier of Sephadex® and Sepharose®.

The Ethiopian Calamity

THE attractions of Ethiopia to the tourist are substantial. Daily flights from Europe to Addis Ababa make it an easily accessible country. The last leg of the journey is from Asmara, in Eritrea, to Addis. Beneath this spectacular flight lie the Ethiopian highlands and the extraordinary churches at Lalibela, hewn directly out of the rock. Beneath the flight path and to the east of it, also lie tens of thousands of dead, in regions now gripped by as bad a famine as relief workers have ever encountered.

The region worst affected lies between Makale in Tigre and Dessie in Wallo. In this area there is one rainy period a year, from June until early September; this is the summer monsoon season. As Winstanley pointed out in *Nature* (245, 190; 1973), mean summer rainfall has recently declined from 165 to 100 mm per year for a set of stations across the Southern Sahara to Khartoum. It is this rainfall which makes much of the middle levels (up to 1,500 m) of Ethiopia suitable for cultivation and grazing, and it is its failure that has led to the famine.

In 1972, crops such as millet, maize and sorghum could not be planted. Thus by September 1972 the tragedy had begun. Between then and May 1973, 80% of the cattle were lost and there were smaller losses of camels. In May, the international organisations working in Ethiopia switched their efforts from development to relief and a plea went to the UN World Food Programme for assistance. Aid did not materialise from this source for several months and meanwhile the Ethiopian government, with organisations such as Oxfam and Christian Aid, were trying to cope in a region in which adequate roads were practically non-existent. For several months, however, the world at large was allowed to know nothing as the government kept a very low profile. Meanwhile the Sahelian countries were forthcoming about their similar troubles and received early aid. This cover-up persisted until Ethiopian students in Addis heard of the disaster and approached Mr Jonathan Dimbleby. The result was the powerful film shown on Thames Television two weeks ago. Mr Dimbleby has since broadcast an appeal for financial support for a relief programme which seems destined to continue for at least a year. And still the full extent of the famine is unknown, because Tigre province includes inaccessible villages in which it is feared more may have died.

What can be done about this terrible disaster? There is, of course, a continuing need for money to support the concerted actions of the voluntary organisations. There is also a need for technical, particularly medical, personnel to do a short tour of duty in the area. There are, however, many broader issues to face. This catastrophe had been foreseeable since September 1972 and yet nothing was done when there was still time. Further, the severe drought conditions south of the Sahara this year did not seem to alert anyone to the possibility that Ethiopia was having similar problems. One cannot be sure, even now, that all affected regions have been identified—is southern

Sudan free of trouble, for instance? The situation in Ethiopia here and now could have been surmised both by earlier observations in Ethiopia and present observations elsewhere. There is even a large American military communications facility within 150 miles of the region. Yet it needed a television programme to alert the outside world.

No doubt there will be proposals for more technology to improve our understanding of climate, more satellites to keep watch, more equipment in the field, better drought-resistant plants. One cannot but hope that science will provide some future comfort. The central issue, however, has no technological solution; it is a social and political problem and is seen in a most exposed form in Ethiopia. It springs from pride in external relationships and a lack of understanding in internal ones. The ruling race are the Shoans, highlanders centred on Addis, and even a sympathetic observer describes them as "proud, aloof, self-sufficient". It is unlikely that they understand the ways of the herdsmen and farmers in Wallo and Tigre. They certainly know little of the character of the nomadic Danakil people. The present situation finds the central government ill-prepared mentally, however much aid they may distribute. Worse, there has clearly been a great unwillingness to allow external publicity and this can only be attributed to misplaced pride and a fear of loss of tourist income.

It is obvious that as long as governments all over the world are too proud to think beyond national solutions to human problems, and relief agencies are hamstrung by political sensitivities, such tragedies will occur with regularity.

100 Years Ago

THE following awards have been made by the French Geographical Society :—2,000 francs to M. Dourniaux-Dupéré, who has just set out for Timbuctoo; this gentleman has also received a similar sum from the Minister of Public Instruction; 2,000 fr. to M. Francis Garnier, to aid him in his explorations along the Blue River in China, and which have Yun-nan and Tibet for their objects; 1,500 fr. to MM. Marche and Compiègne, who have already proceeded a considerable distance along the course of the Ogowe with the design of penetrating as far as the great African lakes, and joining Livingstone.

From *Nature*, 9, 33, November 13, 1873.

The Problem of Compensation for Antenatal Injuries

Dr R. G. Edwards of the University of Cambridge puts forward some personal opinions arising from a discussion at the Institute of Advanced Legal Studies on aspects of fair compensation for injuries sustained before birth.

I WISH to discuss certain points about Working Paper No. 47 of the Law Commission (January 1973) on injuries to unborn children. This proposes statute law for liveborn children suffering antenatal injury to claim damages where negligence of another person can be proven. The concern by lawyers for children with handicaps should be widely welcomed. I have some misgivings, however, about the nature of the proposals, for the correct approach to helping these children should not involve compensation by proof of fault. My doubts arise on several scores:

- The situation created by changes in drug testing methods since thalidomide;
- Difficulty in deciding the causes of many prenatal injuries;
- The possibly complex social consequences arising from legislation, for parents, offspring and doctors;
- The potential unfairness of such legislation to children with birth defects unable to claim compensation under it.

I would also like to explore the possibilities of other approaches to the fair treatment of injuries to foetuses before livebirth.

Causes of birth defects

Many children are born handicapped to varying degrees, and estimates vary between two and six per cent, partly through differing opinions on the nature of the anomalies, and partly because some are manifest long after birth. Some of these handicaps arise genetically, and others through the effects of teratogens during pregnancy. Often there are difficulties in separating the relative contribution of genetic and environmental effects, and interactions between them, and in many cases of birth defects the parents or doctor in attendance will have contributed, accidentally or otherwise.

Teratogens are evidently the main concern of the Commission, and deserve an opening comment. There are practically no guidelines at present in United Kingdom law on compensation for such injury. The unsatisfactory nature of this situation has been highlighted by the recent social debates on compensation for thalidomide children. The funds awarded to these children are obviously a wonderful uplift to them and their parents, and their financial difficulties, at least, should be over. Yet, as well as

the manufacturers, many people and agencies, including the Health Service, were involved in events leading to the thalidomide situation. Responsibilities for drug testing in pregnant animals and for the nature of the tests were diffuse or unrecognised, and fell largely on the manufacturers. This situation has changed since thalidomide, for the governmental Committee on Safety of Medicines now tests new drugs and issues recommendations. In my view, legislation will have to accept this new situation and adapt to it, for a great deal of responsibility for any foetal injury through drugs taken by the mother must now fall on this committee.

My next reservation about the proposed legislation concerns the difficulty in deciding the cause of many congenital defects, for a handicap arising genetically could be mistakenly attributed to exposure to drugs or trauma during pregnancy. There must be many pregnant women carrying a foetus with a genetic defect who are exposed to a potential teratogenic agent, and many misinterpretations in deciding the cause of damage to the child. Indeed, some have already arisen, as judged by some cases in common law. A child was awarded damages for 'imbecile mongolism', judged to arise through injury involving the mother at one month of pregnancy¹. From what we know today about mongolism (trisomy-21), these damages must be unjustified; either a medical misdiagnosis or a miscarriage of justice has occurred, for the chance of a succession of simultaneous chromosomal changes in the cells of a 1-month-old foetus can almost certainly be totally excluded. Similar doubts about the justice of the award were voiced by a dissenting judge in this case. Many of the examples given in the Commission's report appear to be questionable, for club feet and epilepsy evidently have a distinct genetic component²⁻⁴.

Such difficulties seem bound to arise in analyses of the effects of the teratogenic agents quoted in the report; drugs, trauma, X rays and disease. Teratogens usually exert fairly specific effects. One criterion adopted by teratologists is that the type of damage caused must be typical of the agent and of the time during pregnancy at which it was administered. Clear proof of the

effect of teratogenic agents in man will be difficult to obtain; perhaps they could be shown to induce similar anomalies in animal foetuses, but even so the relevance of these observations to man could be questioned.

Trauma is seldom discussed as an agent causing foetal anomalies—foetal death is a more likely consequence. Hardly a case of foetal deformity due to trauma is considered in textbooks, except very recently⁵. The evidence available is shown to be extremely limited indeed; a direct blow to the foetus might inflict damage without death, but clear examples are very hard to prove. Some fairly bizarre examples might arise, such as anoxia following the death of the mother before Caesarean delivery, or accidental damage during surgery, but these hardly seem worth such weight of legislation. Radiation damage is now well recognised, and while mistakes can arise through negligence the best solution to an accidental heavy exposure to X rays might be to abort.

Disease raises very difficult problems. Since it properly includes the effects of German measles and other teratogenic viruses, are there to be penalties for spreading these conditions in a community? The social problems could become even more complex, for foetal handicaps arising from this source would probably be due to parental negligence, so that questions of actions in law by children against their parents would arise, as I shall discuss below. There have been rare cases where the use of contaminated blood⁶ or semen by doctors has led to claims in common law by the deformed child.

Problems in claiming compensation

Much of the proposed legislation could involve claims by children against parents, for example, in the case of congenital syphilis, and once begun such claims could spread to many other situations. Some habits of the mother can impair foetal growth: low birth weights and anomalies in offspring have been reported if the mother smokes or drinks alcohol during pregnancy. There could be grounds for action by children against parents for genetic defects; for example, should a second child have deformities similar to those in an earlier child then the parents might be accused of negligence in the second conception. Claims could even be brought by children for a defective genetic constitution, bastardy or being born half-caste. If the suggestion that these situations could lead to litigation appears to be extreme, let me offer the

defence that these topics have already been discussed elsewhere and some common law cases have actually been heard in court already⁶. The potential upsets to family and social life resulting from numerous claims against parents by children led one court⁷ to decide in favour of the parents even though they were sympathetic to the child's claim, a decision soundly criticised by one legal authority who insisted that such cases should be heard, for if there is a damage then justice must be done⁸. Arguments raised in some related cases led, for example, to justices being compelled to debate the meaning of existence when a child born defective as a result of German measles brought an action against the doctor for wrongful birth⁹.

Further difficult issues may appear with reference to claims arising from agents or acts applied before conception occurred. As far as I am aware, there is no clear evidence, even in animals, to show that specific damage to gametic cells before conception can induce anomaly manifest after birth, with the possible exception of chromosomal imbalance and rare genetic changes. With respect to teratogens, the available evidence shows that eggs and embryos are highly resistant to induced malformation shortly before and after fertilisation. Legislation would therefore be effectively restricted to a few cases. There is also a broader point to be considered concerning the role of doctors and others in helping to establish conception in infertile patients and this is, of course, a field in which I have a direct interest. Many children are now being born after the use of artificial insemination with donor semen, the use of hormones to induce ovulation and other methods of alleviating infertility. Causes for legal action of the liveborn child against the doctor could arise under these conditions, for example, on the choice of the semen donor for AID. A recent report from Germany has implied that children conceived by AID have the right to know the name of their natural father, and doctors refusing to divulge it or creating difficulties in establishing his identity by mixing the semen from several men could be held in law as withholding natural rights from the child¹⁰. Children might be encouraged by legislation to sue the doctor who helped to give life, a possibility more likely than their claiming against parents since the doctor possesses financial resources outside the family. Vital treatment for patients might be withheld because doctors were unsure of their legal position.

These considerations indicate that great care must be taken in framing legislation to cover injury to unborn children. The actual wording of the legislation could lead to further problems. A girl born in 1969 in Vancouver

with defects identical to those of 'thalidomide' children was excluded from many of the benefits of legislation for these children because the real cause of her malformations was unknown (R. B. Lowry, personal communication). I doubt too that the award of damages based on fault to such children is the right or best way to help them in life, with the attendant disadvantages of legal action by a parent or third party sufficiently determined to carry the case through. The legislation would help too few of the children who are afflicted, and probably result in a minority of them obtaining large sums of money while the others depend on state or other benefits. Nor is legislation likely to act as a deterrent, because most injuries will arise accidentally and not with forethought. Granting the right to liveborn children to sue for uterine damage could lead not only to cases of Wrongful Life, but to the more complicated problem of Wrongful Death, in which stillborn foetuses can be the subject of claims, or even have claims brought on their behalf^{10,11}. When these daunting aspects are related to the problems outlined above there would seem to be good cause to search for another method of dealing with foetal injury.

Possible alternatives

An alternative approach can be discerned in existing institutions. The Pearson Commission on Civil Liability and Compensation for Personal Injury has recently been established to consider how compensation should best be payable and financed in respect of death or personal injury arising in various ways, and it will consider antenatal injury. Legislation has already been passed in the United Kingdom to help disabled people (including disabled children) although there are some grounds to believe that the legislation is not being satisfactorily implemented¹². This statute should be fully implemented to provide generous rehabilitation facilities by the state to all children with congenital injuries, whatever the nature of their origin, and so increase the effectiveness of the measures now available. The statutory provisions should be sufficiently generous to take care at least of the medical and social urgencies associated with physical handicap, education, vocational training and employment, and protect the parents as far as possible from suffering and financial loss; some countries have already taken such steps¹³. An important aspect in financing could be to establish a system of "liability without fault" for antenatal injuries, such as the Pearson Commission is considering. Insurance or other systems would be needed to raise funds.

A further lead can be gleaned from the work of the Committee on Safety of Medicines which has statutory authority to oversee and control new

developments in its field. This or another committee could be given wider authority to extend current schemes, mostly local, to monitor the incidence and type of birth defects (chronically sick and disabled persons, including newborns, are now registered by local authorities under the Chronically Sick and Disabled Persons Act (1970)¹⁴). It could also take some of the responsibility for advising and helping doctors and others in making decisions about the value of new methods, and undertake some responsibility to oversee the rights of foetuses. A danger of such a committee might be delay in the application of new methods, unless such developments were excluded from the scope of its deliberations. Within this framework, some organisation might be created to oversee conditions in this field, if necessary having the right to bring actions for negligence against offending parties, and providing legal and medical help where needed. In a different context, compensation for injuries arising to adults through criminal or other action can be awarded by a board, and guardians for unborn children have been legally appointed in the past⁶. I do not know if such compensation could be conferred within our legal situation, although funds can be provided in various ways, for instance, by Royal Prerogative exercised by the Home Secretary in the case of injuries through criminal action.

Ultimately, expenditure of public funds would need legislation, and suitable steps would be required to provide any such committee with appropriate authority. In the meantime, exploratory steps could be taken, or some other systems proposed, in order to avoid many of the pitfalls accompanying legal questions concerning parents, children and other parties, and yet give maximum support to those needing it most—the children afflicted at birth.

Canadian Societies seek More Involvement

from a Correspondent

THE Royal Society of Canada, together with others among Canada's 119 engineering, scientific and technological societies, has been absorbed recently in a searching re-evaluation of its functions and its proper role. One sign of the society's attempts to move with the times was its sponsorship last month of a symposium on energy resources. Some observers in Ottawa are wondering whether the symposium reinforced, rather than changed, the society's public image as an ultra-conservative club for senior scientists, as the meeting was almost entirely devoid of either controversy or confrontation. It is worth recapitulating some of the background to this attempt at increased involvement.

Last December the Science Council published a study* which recommended a more active role for scientific societies in dealing with the implications of science and technology for society. It was also proposed that the federal government should establish a 'Canadian House of Science, Engineering and Technology' to provide the societies with offices and meeting space for their secretariats.

Written by Professor A. S. West, an entomologist from Queen's University, the study also noted the following difficulties facing most Canadian scientific societies:

- They are small and compete with larger counterparts in the United States;
- They have low fees and small incomes, yet must cope with the expense of bilingualism;
- Their young scientists are too little involved and often have a poorly developed social conscience.

Professor West did his study under contract from the Science Council of Canada through an organisation known as SCITEC (the Association of the Scientific, Engineering and Technological Community of Canada). SCITEC was formed in 1970 in response to the complaint of members of the Senate special committee on science policy (the Lamontagne Committee, see *Nature*, 245, 406; 1973) that they could not find a single voice to speak for all of Canadian science. It has since abandoned any pretence of fulfilling such an oracular function, but is now the principal contender, together with the Royal Society, for leadership among Canadian scientific societies.

The two societies are quite different

in purpose and structure. The Royal Society is the Canadian equivalent of an academy of science, but SCITEC is somewhat analogous to the British or American Associations for the Advancement of Science. Both groups claim, however, some similar functions. One of these is to increase public understanding of scientific issues; SCITEC itself had already held a symposium on the social and economic implications of the energy situation.

The report of the Lamontagne Committee proposed that the two organisations should not compete but cooperate, by defining and dividing their functions. "The Royal Society," it said, "with its reservoir of scholarship represented by its fellows and scientific panels could concentrate its national activities on the use of science for policy—on scientific and technological studies dealing with Canadian issues. SCITEC, as an overall spokesman for the engineering, scientific and technological societies, could specialise on policies for science and technology—on broad issues concerning scientists, engineers, and technologists in the exercise of their professions."

The Royal Society's latest symposium, however, seems to some to cast doubt on the claim of its president of last year, Professor Tuzo Wilson, that the organisation is being revitalised. For although the subject matter (energy) was highly topical, the approach and the choice of

speakers and subjects seemed conventional and the papers added nothing new to an already much-debated problem. What little discussion was allowed, was conducted by means of written questions; a practice that brought a formal complaint from some of the younger members of the audience.

There were some good things. The society took unusual steps to publicise the venture and had a good attendance as a result (some 300). The review papers provided a mass of information. And three of the thirty-five speakers departed from the predominant theme—how to increase the energy supply—by proposing that perhaps what is needed is a whole new policy of moderation of life styles to slow down the rate of increase in the use of energy. One of the three was former chairman of the Economic Council of Canada, John J. Deutsch.

In his report, Professor West spoke of the need of a major overall co-ordinating organisation to increase the involvement of Canadian scientific societies, and he quoted an unnamed scientist as saying it must be "of such stature and articulation that the public will accept its pronouncements on the same plane at least as those of the Science Council."

The impression remains that, in spite of recent attempts, neither society has yet succeeded in fulfilling that role.

MEDICAL JURISPRUDENCE

Transplants and Murder

by our Washington Correspondent

A MURDER trial which is to open in California on December 18 will be the venue for a legal battle over the precise definition of death, and the outcome will have significant implications for transplant surgery. At the centre of the trial is Andrew D. Lyons, who is accused of shooting Samuel Moore, a 29-year-old California man, in the head on September 10, 1973. On September 12 Mr Moore's brain showed no signs of electrical activity, he was unable to breathe, and did not respond to stimulation. He was then pronounced "neurologically dead", and his heart was used in a transplant operation performed by Dr Norman Shumway, a Stanford heart surgeon who has performed some 65 transplants; 23 of his patients are still surviving.

Californian law allows transplants to be performed provided that the donor has been pronounced dead, but no pre-

cise legal definition of death is given. In this case, according to the *New York Times*, Moore's wife and mother had given permission for the transplant, Moore was pronounced dead on the grounds of a lack of cortical activity, and his heart was removed while still beating. Clearly, the concept of brain death is going to play a large part in the trial. There is, however, one close parallel case in American legal history. Last year, a team of surgeons from the Medical College of Virginia was acquitted of a charge of killing a 56-year-old black man to use his heart in a transplant operation. In that case the donor suffered brain damage as the result of a fall, and he was pronounced dead when an electroencephalogram showed no signs of electrical activity in the brain. His heart was subsequently removed, while still beating, and used in the first heart transplant carried out in Virginia. The jury in the trial had little difficulty in deciding that the donor was legally dead when his heart was removed, and the doctors were acquitted.

Short Notes

Le Ballon Rouge

THE first part of a new Franco-Soviet drift-balloon project, to investigate high altitude phenomena at Arctic latitudes, will soon begin with the launching of a balloon from a test site in Sweden. The experiment, called "grebenka" (comb), is intended to monitor charged particles and associated phenomena during the aurora borealis, and will consist of two series of balloon flights, the first in winter 1973-74 and the second a year later. The flights will be at an estimated altitude of 35 to 45 km, and due to the strong westerly prevailing winds are expected to proceed eastwards from Sweden over the northern islands of the Ural ridge for a distance of some 2,000 km.

According to *Pravda* (October 31, 1973) the balloon is to be tracked throughout by radar and the data gathered are to be transmitted to the ground station and recorded there for subsequent analysis—a somewhat surprising procedure, since it is explicitly stated that one of the objects of grebenka is to monitor those conditions in which radio communications break down.

Skylab Launch Date

THE launch of the third and final crew of Skylab has now been scheduled for November 10. This is earlier than some astronomers had hoped, and it seems that Skylab will, after all, be unmanned for part of the period in January when Comet Kohoutek is expected to be at its most spectacular. But according to NASA "consumables will be closely husbanded to keep open an option to extend the final mission to about 70 days". Kohoutek will reach perihelion on December 28, and a "standard" 56 day mission would terminate on January 6. But if the mission does run until January 20, 1974, or thereabouts, there would be opportunities for studying ice and snow distributions in the northern hemisphere, and the start of the growing season, as well as making further observations of Kohoutek. The two earlier Skylab missions lasted for 28 and 59 days.

Russian Nuclear Activity

THREE underground nuclear explosions were fired on October 26 and 27 in the Soviet Union in the most vigorous burst of activity ever recorded. One shot was in the normal testing ground near Semipalatinsk, and a second was on the Arctic island of Novaya Zemlya. This latter was the largest ever fired underground in the Soviet Union and was comparable in yield to the Cannikin blast in the Aleutians in 1971. Several aftershocks were recorded from the event. The largest had a magnitude of 4.6. This is the first occasion on which

aftershocks of Soviet tests have been reported. The third shot was in the Urals region and was in all probability for peaceful purposes. Soviet Plowshare activity in the last two years has been at the high level of between ten and twenty shots each year.

Winning Sargassum War

ATTEMPTS to clear the Japanese seaweed *Sargassum muticum* from the Isle of Wight and Portsmouth harbour are proving successful. The weed is being collected fortnightly and the majority of fronds are only 20 to 30 centimetres long—the length to which they grow in about a fortnight.

As yet a committee formed by local authorities with representation from the Nature Conservancy the Ministry of Agriculture, Fisheries and Food, the local river authorities and the Natural Environment Research Council (NERC) has still to meet to decide if money is to be allocated to help with the eradication.

To date the £500 spent on clearing the weed has all come from Portsmouth Polytechnic, the Nature Conservancy and a local trust, with studies of the seaweed's behaviour being financed by NERC. Local authorities have still to make a contribution.

Dr Gareth Jones, of Portsmouth Polytechnic, who has been organising the eradication programme says that "at the moment, there is no real threat as we are digging the seaweed up, but come next spring there very well could be a problem. It is under control now; it does not necessarily mean that it will be by then".

To keep the weed—which grows at the alarming rate of 1 to 2 centimetres a day and which could create a hazard for shipping, cover oyster beds and foul beaches—under control, a full-time appointment is needed. To ensure that the weed does not become established in Britain the young plants that are springing up will have to be removed regularly for the next 2 or 3 years.

Centrifuge Setback

THE United States gas centrifuge programme for enriching uranium received a severe setback on October 20, when a model centrifuge was destroyed in an accident at the Oak Ridge plant in Tennessee. The accident, which was made public by the Atomic Energy Commission last week, occurred when an advanced model centrifuge failed at high speed, damaging several other units and releasing 4 ounces of uranium hexafluoride. By good chance, the accident occurred on a Saturday, when few people were in the building, and nobody was hurt. What effect the accident will have on the programme remains to be seen, and the AEC is not yet prepared to give many details away. An investigation is under way, however, and its

findings will determine the extent of the adjustments, if any, that will have to be made in the design and operation of its other centrifuges.

USGS Gets the Lot

THE United States Geological Survey has inherited all the seismological, geomagnetic and earthquake research programmes from the National Oceanic and Atmospheric Administration (NOAA). Prime object of the transfer is to save money by consolidating the Geological Survey's extensive activities in Earth sciences with those of NOAA, and to cut down on the duplication of effort which has been going on, particularly along the San Andreas Fault. The first stage of the transfer took place in June, when NOAA's Earthquake Mechanisms Laboratory in San Francisco was merged with the Geological Survey's National Center for Earthquake Research in Menlo Park. The second stage, announced last week, completes the transfer of NOAA's entire programme, including management of the Worldwide Standard Seismograph Network, the National Earthquake Information Service and all the seismological observatories except for three needed for the tsunami warning system. As far as the first stage of the transfer is concerned, it seems that difficulties have arisen because the two laboratories were doing parallel work, and redundancies are expected.

Comet Kohoutek Limited

Two London businessmen have come up with the bright idea of registering the name 'Comet Kohoutek' for business purposes. Operating as Comet Kohoutek Limited, they are at present negotiating with "a number of national advertisers" in Britain intent on using the comet to promote such items as toys and fireworks. A spokesman for the company said this week that one national newspaper has already come to an arrangement with Comet Kohoutek Ltd about use of the name, but he could not give any details before the promotion gets under way. Members of the scientific and journalistic communities will no doubt be relieved to learn that they can use the name Comet Kohoutek in describing the comet without fear of prosecution; but anyone who is based in Britain and wants to market, say, a new drink called 'Kohoutek—the fizz with a wizz' will have to pay for the privilege. Comet Kohoutek Ltd operates from 11 Ranmore Court, Catherine Road, Surbiton, Surrey KT6 4HE.

"It will add considerably to our inadequate knowledge in the ill-documented field of . . ."—Book advertisement in a recent issue of *Nature*.

NEWS AND VIEWS

Hot Spots on X-ray Sources

THE study of X-ray sources is one of the great success stories of present-day astrophysics. For objects like Cen X-3 or Her X-1 it is possible to build up a model which is based, almost entirely, on qualitative arguments. Thus the X-ray observations of these sources show short period fluctuations in brightness, on a time scale of seconds. No simple astronomical object can oscillate or rotate as fast as this unless it is considerably denser than a white dwarf. The next densest type of object is a neutron star, and so the first qualitative conclusion is that the X-ray emission comes from neutron stars (at least).

Superposed on the short period fluctuations there are longer period variations, very reminiscent of those seen in eclipsing binaries. Optical astronomers have long been very fond of such close binaries, for their detailed observation readily permits the determination of interesting physical parameters, such as the masses and the radii of the partners, and their distance apart. More than that, it has been realized in recent years that the close proximity of one star to another may lead to great perturbations in the behaviour of one or both members of the pair. The most important of these effects is a strong tidal distortion, which allows mass to stream out of one star and into the other.

These ideas have a counterpart in the case of the X-ray sources. The generally accepted model has it that the binary consists of a rather ill-matched pair of stars. The primary star is large and diffuse; once in each period it eclipses the secondary, which is very compact, and which also emits the X rays. Because the secondary emits so much energy (in the form of X rays) it will cause a considerable modification in the properties of the atmosphere of the primary. It is quite possible that most of the radiation from the primary is really derived from energy generated on the X-ray source. It is equally likely that the uneven heating caused by the X-ray source will lead to the loss of mass from the outer layers of the primary.

Here is a crucial point in the whole description, for it is this very gas, which the X-ray source extracts from the primary, that finally falls on the neutron star and provides the energy for the X-ray emission. The energetics of the process can be quite satisfactorily understood. It requires of the order 10^{15} erg of energy to pull one gram of matter off the surface of the primary. But about 10^{20} erg can be recovered for each gram that falls on the neutron star. Once the pump is primed it should go on running quite satisfactorily even if only a small fraction of the gas finds its way to the neutron star, and even if most of the X-ray energy escapes into space.

Now how does this gas get down onto the surface of the neutron star? From the theory of pulsars one knows that neutron stars often have strong magnetic fields. In the case of the X-ray source the infalling material, which will of course be highly ionized, must be guided down to the surface along the lines of force of the magnetic field. The outermost lines of force in the field are those which originate at the magnetic poles.

So the gas falls down a pair of 'funnels', each of which terminates at a magnetic pole. This is where the potential energy released in the fall is turned into X rays. As the X-ray source turns the hot spot(s) can intermittently be seen. Hence the pulsation of the source.

This is indeed a persuasive picture, but it is based on more hand-waving than even an astrophysicist is likely to be used to. Nobody can yet describe exactly how the uneven heating by the X-ray source affects the thermal balance of the atmosphere of the primary, nor how much mass loss results from it. Nobody can yet say how the circumstellar plasma will interact with the low frequency radiation from the rotating neutron star. Finally, nobody can yet give a hydromagnetic description of the process by which the neutron star captures the plasma. But at least a start has been made on a description of the last stages of the infall.

In an article in last Monday's issue of *Nature Physical Science* (246, 1; 1973) Davidson discusses the mechanics of the plasma flow in the region just above the magnetic poles. Here the infalling gas is constrained to move along the lines of force, which are almost rigid because the magnetic field is so strong. As it comes close to the surface, the gas is decelerated by radiation pressure. But because it is slowed down, it must lose energy, which it gives up to the radiation field, thereby adding to the radiation pressure. It turns out that the radiation cannot escape upwards against the gas flow. Instead it leaks away through the sides of the funnel.

Comparison shows that this relatively simple sequence of ideas can be brought into good agreement with observation. A set of quite homely parameters describes the mound of gas where the X rays are produced. It is about as high as the Post Office Tower, covers an area somewhat smaller than Hyde Park, and the mass per unit area in the mound is about the same as the mass per unit area in the Earth's atmosphere.

It seems out of the question that these predictions will ever be verified by direct observation. On the other hand, it is unlikely that anyone will ever seriously challenge these conclusions, except perhaps in some minor way.

F. D. K.

Lymphocyte Trapping

CELLULAR immunologists have been so enthusiastic in their pursuit of knowledge that they have described many phenomena of which, at present, the biological significance is uncertain. Allogeneic inhibition, for example, which related to various situations in which foreignness of environment was apparently inhibitory to a wide variety of cell populations, was popular a few years ago. Nobody knew whether it was significant in relation to the growth of a tumour, or a kidney allograft, but it was, and presumably still is, an interesting phenomenon. Perhaps the discovery of allophenic mice in which genetically very disparate cells seem to exist in cheek and jowl in perfect

harmony presaged the decline from favour of the notion of allogeneic inhibition. Lymphocyte trapping, the subject of a communication by Frost and Lance on page 101 of this issue of *Nature*, is similarly a phenomenon widely thought about but of which the biological significance is unclear.

In earlier papers Lance and his colleagues have described how, when mice are injected with ^{51}Cr -labelled syngeneic lymphocytes during an immune response, the label appears preferentially in the responding lymphoid organ. Other immunologists have shown a small drop in lymphocyte output from lymphoid organs in the early stages following antigenic stimulus, and it seemed to Lance and his colleagues reasonable to suppose that during an immune response there were alterations in the flow of lymphocytes through the responding organ such that more cells were, in the Lance terminology, trapped. It has been found that although trapping can occur during an immune response, the mechanism is more or less independent of the immunological status of the organism in which trapping is demonstrated.

In their new paper Frost and Lance describe how trapping is much reduced in both the spleen and lymph nodes during a response to antigen in mice, which also carry certain transplanted ascites tumours. Ascitic fluid injected into non-tumour bearing recipients had a similar depressing effect on the trapping system. As it was shown in other experiments that the same tumours growing in a solid condition failed to alter the capacity to trap—which indeed was augmented in lymph nodes draining the site of implantation of the tumour—the authors could not argue that malignancy *per se* was having an immunosuppressive effect. Nevertheless, they postulate that part of the immunosuppression sometimes found in advanced cases of malignancy could be due to failure of trapping.

It will be of considerable interest to find out whether the mice with ascitic tumours had similar factors in their serum to those found in shock plasma which can inhibit some of the activities of the reticuloendothelial system. It could be that trapping is a manifestation of stimulation of the macrophages and that in various 'stress' situations trapping is reduced because of partial failure of excitation of macrophages.

From a Correspondent

EPIDEMIOLOGY

Sexual Transmission of Hepatitis B

from our Medical Virology Correspondent

THE epidemiological concepts of hepatitis B infection have recently undergone a significant change. The demonstration that the hepatitis B agent is infective by mouth and the finding that the infection is endemic in closed institutions, the prevalence of infection in adults in urban communities, the carrier rate and age distribution of hepatitis B antigen in different geographical regions and the relatively high incidence in poor socioeconomic environments, have altered the epidemiological dogma that hepatitis B is spread exclusively by blood and blood products through the direct parenteral or percutaneous route. Some evidence is now also available for the transmission of hepatitis B by intimate personal contact and possibly by the venereal route.

In 1971, Hersh and colleagues (*New Engl. J. Med.*, **285**, 1363) presented the case history of six patients with hepatitis B infection. Although the precise mode of transmission from a man to his close female companion or companions was not clearly defined, a non-percu-

taneous route was strongly implicated. The first patient developed hepatitis 3 months after blood transfusion, hepatitis B antigen persisted in his blood and 3 months later his wife developed antigen-positive infection. The second patient was a drug addict who contracted acute hepatitis B; his wife, who was not an addict, developed hepatitis without jaundice 4 months later and the antigen was detected transiently in her serum. The third patient suffered from hepatitis and his girl friend developed a similar illness 3 months later. The fourth patient was a technician working in a renal dialysis unit and hepatitis B antigen was detected in his serum during routine examination. Three of his intimate female contacts developed acute hepatitis B infection. Another patient developed acute hepatitis B; her husband had chronic hepatitis and the antigen was repeatedly found in his serum. The sixth patient in this series was a drug addict, who died of acute fulminant hepatitis. His girl friend, who did not take drugs, suffered from acute hepatitis 2 months later.

CEA-like Substance on Erythrocyte Membranes

IN 1965 Gold and Freedman described an antigen which was thought to be specific for human tumours and foetal tissues of endodermal origin. Called carcinoembryonic antigen (CEA), it was a finding of potentially great importance. But it was not until about four years later, when the first CEA radioimmunoassays were reported, that the CEA story really began to interest the scientific community. Such methods suddenly gave rise to the possibility of being able to perform early screenings for the deadly colonic carcinomas, at a time when the disease would not yet be clinically apparent. Sadly, more recent experience has shown that this hope was over-optimistic; for colonic CEA, or substances cross-reactive with it, has been detected by various methods to occur in the urine, plasma, or faeces of patients with both neoplastic and non-neoplastic (usually inflammatory or regenerative) disorders, and even, albeit in much smaller amounts, in apparently healthy subjects.

It is conceivable that the occurrence of CEA (a glycoprotein molecule), in non-neoplastic conditions, could be, in part, due to the release of glycoprotein moieties from the various types of cells which have cross-reacting antigenic specificities with known colonic carcinoma CEA. This possibility is strengthened by results of Nery, Bullman and Barsoum described in *Nature New*

Biology next Wednesday (November 14).

Noting that the levels of CEA in the plasma of fresh blood specimens may increase on storage of the whole specimen, Nery *et al.* set about to see if CEA-like cellular components are gradually released into the plasma by red cells. Using isolated red cell membranes they indeed detected CEA by radioimmunoassay; furthermore, red cells from cancerous and non-cancerous patients as well as healthy control donors were positive and all gave similar mean values. Further analysis of the CEA-like substances demonstrated that they have glycoprotein and glycolipid structures, partially cross-react immunologically (as defined by double diffusion in agarose) with known colonic carcinoma CEA, and have molecular weight characteristics similar to colonic carcinoma CEA. The CEA activity was assessed to be probably more than a single structural entity.

It would seem, as Nery *et al.* cogently point out, that what is known as 'immunologically defined CEA' may in fact represent a family of antigenically related molecules, possessing subtle structural differences, perhaps resulting from impaired cellular metabolism. For those who are concerned with assay of CEA, or indeed of any purified tissue antigen, the implications are self-evident.

Mosley (*Can. med. Ass. J.*, **106**, 427; 1972) reported further data which implicated intimate personal contact. During a study of the secondary attack rates of hepatitis among household contacts of patients treated by maintenance haemodialysis the incidence of the infection among children and non-spouse adults was 1.4%, whereas the rate in marital partners was 20%.

Three more recent studies in London tend to substantiate the possibility that sexual transmission of hepatitis B infection may be a real entity. Jeffries and colleagues (*Brit. med. J.*, **2**, 455; 1973) examined serum specimens from 1,650 patients attending a venereal disease clinic in London. Hepatitis B antigen was detected in the serum of 2 out of 553 (0.4%) female patients; 1 out of 520 (0.2%) European male heterosexual patients; and in 11 out of 282 (3.9%) European male homosexuals. The possibility of venereal transmission of hepatitis B infection in homosexuals had been suggested previously. Many of the homosexual patients in this survey attended the clinic repeatedly with genital and skin sores and transmission of hepatitis may have occurred through these lesions.

In another survey conducted by Fulford and colleagues (*Lancet*, **i**, 1470; 1973), sera from 974 patients attending another clinic for sexually transmitted diseases were tested for hepatitis B antigen and antibody. The antigen was detected in the serum of 1.7% of the clinic patients and antibody in 4.8%, whereas in the new blood donor population the overall prevalence was 0.2% and 0.4% respectively (bearing in mind, of course, that these two populations are not strictly comparable). Statistical analysis revealed significant differences for sex and marital status, with both the antigen and antibody-positive groups containing a higher proportion of single men. Highly significant correlations were found for the hepatitis B antibody group with a history of both syphilis and gonorrhoea. Patients with antigen had a significantly higher frequency of gonorrhoea. It was again noted that the group with hepatitis B antibody (which constitutes evidence of past infection with hepatitis B virus) contained a much greater proportion of homosexuals and also promiscuous patients of British origin. In yet another investigation on the mode of spread of acute hepatitis B (Heathcote and Sherlock, *Lancet*, **i**, 1468; 1973) sexual contact or close domestic contact seemed to be the most likely source of infection in 40% of 67 patients studied.

It seems, therefore, that the concept of hepatitis B as an important sexually transmitted infection merits careful consideration not only because it represents a new epidemiological entity but also because prevention may be feasible.

RIBOSOMAL RNA

Control of Synthesis

from a Correspondent

ALTHOUGH the multiple ribosomal RNA genes (rDNA) of *Xenopus laevis* are probably the best characterised of any eukaryotic organism, very little is known about the control of rRNA synthesis. The genes are linked at one locus which is very closely associated with the nucleolus organiser region, since a deletion, which obeys simple Mendelian rules, eliminates both rDNA and nucleolus organiser together. Each gene consists of two parts; the transcription unit which produces ribosomal precursor RNA containing 18, 28S and excess transcribed spacer sequences, and a spacer unit which is not transcribed. Another species of *Xenopus*, *X. mulleri*, also has multiple rRNA genes and a detailed comparison (Brown, Wensink and Jordan, *J. molec. Biol.*, **63**, 57; 1972) between the rDNA of *mulleri* and *laevis* has revealed several interesting things.

Briefly the two sorts of rDNA have different base compositions which is reflected in the slightly greater buoyant density of *laevis* rDNA. Even though it is impossible to distinguish between *laevis* and *mulleri* 18 and 28S rRNA on the basis of size, base composition, or fidelity of nucleic acid hybridisation, the two precursor rRNAs may be distinguished by nucleic acid hybridisation in the presence of excess 18 and 28S rRNA. The species difference is thus due to altered base sequences within the transcribed and non-transcribed spacer regions.

In the latest issue of the *Journal of Molecular Biology* (**80**, 217; 1973) Honjo and Reeder describe the synthesis of rRNA in hybrid frogs produced by crossing *Xenopus laevis* and *mulleri*. Using the notation l^+/l^+ and m^+/m^+ to describe the homozygous wild type ribosomal genotype of *laevis* and *mulleri* respectively and l^-/l^+ to describe the *laevis* heterozygote ribosomal genotype (a similar m^-/m^+ genotype has not been described in *mulleri*), it is possible to write the genotypes of the four possible hybrid animals as follows: l^+/m^+ , m^+/l^+ , l^-/m^+ , and m^+/l^- , given that the maternal contribution is written first.

What Honjo and Reeder have done is to measure the relative transcription of *laevis* and *mulleri* rDNA in these four hybrid types at different stages of development as well as in adult animals. Since it is impossible to distinguish 18 and 28S rRNA from the two species, they had to develop a technique for measuring relative amounts of *laevis* and *mulleri* rRNA based on detection of the non-conserved regions of the precursor rRNA. This was done by hybridisation of a mixture of authentic ^3H -labelled *laevis* precursor rRNA with ^{32}P -labelled precursor rRNA from the

hybrid animal to purified rDNA from both *laevis* and *mulleri* in the presence of excess unlabelled 18 and 28S rRNA. The results are expressed as the ratio (L/M) of $^3\text{H}/^{32}\text{P}$ bound to *laevis* rDNA (L) to $^3\text{H}/^{32}\text{P}$ bound to *mulleri* rDNA (M). They constructed a standard curve of the ratio L/M against the proportion of *mulleri* rRNA in a known mixture of ^{32}P -labelled *mulleri* and *laevis* rRNA and used this for assaying unknown mixtures.

The results of their experiments are briefly as follows: when a hybrid receives *laevis* rDNA (that is, genotypes l^+/m^+ and m^+/l^+), *mulleri* rDNA is repressed; but when a hybrid receives no *laevis* rDNA (that is, genotypes l^-/m^+ and m^+/l^-), *mulleri* rDNA is repressed only if the maternal contribution is *laevis* (l^-/m^+) and then repression is only transitory since by 100 h of development synthesis of *mulleri* rRNA is the same as in the m^+/l^- hybrid which shows no repression of the *mulleri* rDNA.

Honjo and Reeder interpret these results as indicating two pathways for the repression of *mulleri* rDNA. One, due to the presence of *laevis* rDNA, is permanent and not maternally inherited, and the other, due to the presence of *laevis* egg cytoplasm, is maternally inherited and transitory. Clearly these observations may represent two points on the same repression pathway; the cytoplasmic maternally inherited repressor may be identical with the diffusible intermediate operating in repression by *laevis* rDNA, though as they point out the mechanism of repression by *laevis* rDNA may be due to its higher affinity for some molecule in short supply and not to its coding directly for a repressor molecule.

Regardless of the details of the repression mechanism, it seems fair to say that it has something to do with the spacer regions of rDNA since there are apparently no differences between the 18 and 28S rRNA sequences of the two species themselves, and the spacer regions are known to have diverged. This suggestion relies on the assumption that the l^- deletion of rDNA and nucleolar organiser removes no other genetic component which might act as the source of repressor. In this connection it would be interesting to know whether and to what extent the partial nucleolar mutants (Miller and Gurdon, *Nature*, **227**, 1108; 1970; Knowland and Miller, *J. molec. Biol.*, **53**, 321; 1970) of *laevis* will repress *mulleri* rDNA.

Laevis/mulleri hybrids have also previously been used to distinguish between 'chromosome copy' and 'episome' models for rDNA amplification during oogenesis (Brown and Blackler, *J. molec. Biol.*, **63**, 75; 1972). Brown and Blackler found that, regardless of whether *laevis* was the male or female parent, hybrid female animals always amplify

the *laevis* rDNA even though they contain both *laevis* and *mulleri* rDNA complements, which is consistent with the 'chromosome copy' mechanism but not with the 'episome' model since the latter demands maternal inheritance. It is not known at present whether the mechanism for repression of *mulleri* rRNA synthesis has anything to do with the selective amplification of *laevis* rDNA, although the mechanism of rDNA amplification proposed by Crippa and Tocchini-Valentini (*Proc. natn. Acad. Sci. U.S.A.*, **68**, 2769; 1971) based on RNA-dependent DNA synthesis would specifically predict amplification of only *laevis* rDNA if *mulleri* rRNA synthesis is repressed.

WILDLIFE

Death on the Road

from a Correspondent

THE question of what motivates a domestic fowl to traverse a highway has occupied the mind of man ever since roads were invented and chickens were domesticated. This problem was not solved at a symposium entitled "Motorways and the Biologist" which was held at the North East London Polytechnic on October 25, but similar questions were raised; such as the reason why deer and badgers make suicidal excursions across trunk roads and motorways and how they can be discouraged.

D. Venner (Forestry Commission) described attempts to discourage deer from crossing roads in the Forest of Dean by mounting 3-inch square mirrors on posts at the side of the roads which reflect motorcar headlights into surrounding woodland and give animals advance warning of approaching vehicles. The highly predictable nature of deer in both the time and location of crossing roads can be used to advantage in planning the siting of such mirrors. Unfortunately, the data on deer mortality before and after the erection of mirrors are ambiguous and adequately controlled experimentation is needed before this system can be evaluated.

Badgers are also creatures of habit and they often insist on using their well-worn trails between sett and foraging ground even when a motorway is constructed across them. M. Clark and E. P. Ratcliffe described experiences in Hertfordshire and Cheshire respectively in which elaborate attempts have been made to accommodate the inflexible attitudes of local badgers disturbed by motorway construction. In certain situations, where badger trails are well known, special culverts have been incorporated into the design of new motorways, together with badger-proof fencing which channels the animals into the tunnels. Stream culverts can easily

be modified for badger use, but it costs £1,200 to construct a culvert 1 m in diameter especially for badgers. One must admire the motivation behind such expenditure, but so far only circumstantial evidence exists that badgers have demonstrated their appreciation by using these tunnels. It is possible that in the long term a great deal of money could be saved if research into such problems were commissioned before such expenditure was incurred.

The other major topic considered at this meeting was the value of Britain's motorway verges for wildlife conservation. J. M. Way (Nature Conservancy, Monk's Wood) has conducted a survey of the plant life of the M1 motorway between Hendon and Leeds and has found more than 380 plant species on its verges. It is possible to devise management procedures in which the demands of the highway engineer can be reconciled with the desires of the botanist. Some of the most interesting plant communities of verges develop in situations where rocks such as chalk and limestone, which may be exposed by excavation, have not been covered by topsoil after construction. Perhaps arrangements could be made to leave such areas bare. Herbicide treatment is obviously not conducive to a varied flora, nor is it necessarily in the economic interest of those managing a verge. Experiments on cutting frequency reveal that just two mowings, one in May and a second in June, can be effective in maintaining vegetation below 30 inches in height (the recommended level), thus avoiding any herbicide treatment.

The conservation of roadside flora may have some economic as well as amenity value. J. Free (Rothamsted Experimental Station) in a survey of the M1 near St Albans found sixty-seven insect species, of which hoverflies constituted the most important group, carrying pollen on their bodies from a total of thirty-nine plant species. Verges with a high floral diversity may thus act as reservoirs for such beneficial insects.

A further consideration in the conservation of verge flora and fauna is pollution. P. Williamson (Portsmouth Polytechnic) described a survey of lead pollution on the verge of A1 (M) at Catterick. Traffic levels during the survey period were 34,000 vehicles per day. Lead, presumably originating from exhaust fumes, attained levels of 200 p.p.m. in the soil of the central reservation and at the edge of the carriageway. Pitfall traps were used to sample invertebrate populations at various distances from the carriageway and their lead concentrations were measured. Isopoda beside the road were found to contain 700 p.p.m. lead and Diplopoda 100 p.p.m., but despite this the species composition of the invertebrate communities did not seem to be affected by lead. Lead accumulation of this order was not reflected in small mammals, which had liver concentrations of only 10-15 p.p.m. and there was no evidence of further concentration at higher levels in the food chains.

The overall impression given by this conference is that the biologist is not yet in a position to solve many of the ecological problems posed by motorways.

Thiols and Membrane Structure

In the next issue of *Nature New Biology* (November 14) Dupont and Hasselbach describe some extensive changes in the structure of the sarcoplasmic reticulum membrane that ensue when the ATPase is poisoned by thiol reagents. Titration with a mercurial, or with N-ethylmaleimide, reveals that there are ten to twelve reactive thiols per 10^5 molecular weight of protein in sarcoplasmic reticulum vesicles. The two types of ATPase activity that reside in this membrane respond differently to the elimination of free thiols: calcium-activated ATPase decreases linearly while four groups are reacted, whereas the basic magnesium-dependent ATPase evinces slight activation until five of the thiols have reacted, and thereafter falls off rapidly.

That extensive structural changes accompany the reaction of the thiol groups was at once apparent from an increase in turbidity, betokening aggregation of the vesicles. The changes are reflected in progressive alterations in intensity and position of the X-ray

spacings obtained from stacked oriented membranes. These are of relatively minor extent at low levels of substitution, but when more than about four thiols groups have been blocked the character of the X-ray pattern changes in a manner that can be interpreted in terms of the loss of the asymmetric structure which characterises the native membrane. The protein is not released but redistributed so that its average disposition with respect to the plane of the bilayer is symmetrical.

It seems then that substitution of the thiol groups causes the protein molecules to sink into the bilayer, either continuously or, according to a plausible hypothesis offered by the authors, on dissociation of a putative ATPase oligomer, which occurs when a critical number of thiol groups has been blocked. This will expose new protein surfaces and the nature of the interaction with the phospholipids in the bilayer will be changed in such a way as to favour a new and symmetrical structure.

Data Processing

from a Correspondent

ELECTRONIC data processing (EDP) has hitherto been used in very few herbaria, mostly for comparatively small projects, and its scope in the larger herbaria, particularly in Europe where most are located, has been hardly considered. An international meeting at the Royal Botanic Gardens, Kew, from October 3-6, had as its purposes to explore areas where EDP can help in herbaria and associated collections, and to ensure that future developments in the larger European herbaria shall be as far as possible compatible and their results internationally available. The NATO Eco-Sciences Panel acted as sponsor.

After introductions by Professor J. Heslop-Harrison, representing Kew, Professor J. G. Hawkes, chairman of the organising committee of the meeting, and Dr A. Rannestad, representing NATO, the contributions on the first day were chiefly focused on the scope of EDP in herbaria.

J. P. M. Brennan (Kew) described the priorities for EDP in a principal international herbarium, given that staff and finance are limiting factors. R. Ross (British Museum (Natural History)) spoke on the relationship between herbarium records and others, recognising that most important herbaria are associated with ancillary collections or living collections or, in the case of museums, with collections belonging to other disciplines. D. M. Henderson (Royal Botanic Garden, Edinburgh) discussed the problems presented in adapting label data on specimens for EDP purposes. The importance of this aspect is apparent from one of the resolutions passed at the end of this meeting. A. Gomez-Pompa and J. A. Toledo (National University of Mexico) and A. V. Hall (University of Cape Town) described operational schemes in their collections; the Mexican scheme involves a computerised record of the flora of Veracruz.

The general theme of the second day was to consider various EDP systems currently in use to give delegates an opportunity of asking questions and making comparisons. S. G. Shelton (Smithsonian Institution, Washington) described the ambitious and far-reaching Flora North America project—a data bank which uses the GIS system. The general collections at the Smithsonian Institution are recorded by a general-purpose information system called SELGEM, which was described by J. F. Mello. D. J. Rogers (University of Colorado) expounded the well-known TAXIR system devised for taxonomic purposes. The principles of general-purpose filing systems as devised

by the Information Retrieval Group of the Museums Association (IRGMA) were described by J. L. Cutbill (University of Cambridge). This system is basic to the programme for computerising the geological collections at the Sedgwick Museum in Cambridge. S. W. and D. M. Greene (British Antarctic Survey, Birmingham) described the principles behind the computerising of some 30,000 herbarium specimens in the Botanical Section of the British Antarctic Survey. F. H. Perring (Biological Records Centre, Monks Wood) spoke on EDP operations at the centre and made the point that many data can be handled by non-computerised methods, particularly microfilm and microfiche.

Many herbaria are linked with botanic gardens, the computerisation of whose living collections presents, of course, parallel problems. R. A. Brown (American Horticultural Society) described the recording system used at the Plant Records Center where a standardised system has been developed for recording and reporting information on plants cultivated in the principal North American botanical gardens and arboreta. At present the data files contain more than 170,000 records. This theme was later developed by J. Cullen who described the operation of the living plant record system at the Royal Botanic Garden, Edinburgh.

EDP systems in herbaria thus have an interface with similar systems for living collections. With the probable future international development of genetic resource centres, this is likely to increase in importance. Other discussions included the important application of herbarium label data to computerised mapping of plant distributions as developed in the National Herbarium of Canada in Ottawa. A further example was provided by D. B. Williams (British Museum (Natural History)) who discussed the link often found in principal museums between botanical and zoological collections, and described some of the special problems of the latter.

During the conference, recommendations were invited from participants, which were edited by a drafting committee, and put to discussion and vote by the delegates on the last day. The following is a summary of the principal resolutions which were passed, all of them either unanimously or by a very large majority:

(1) Data banks for plant collections should have a common minimal-standard set of descriptors based primarily on label data.

(2) A working party is to be set up to advise European herbaria on the set of descriptors referred to under (1).

(3) Individual herbaria should co-operate with national organisations, and national organisations should be en-

couraged to work through the International Committee on Museums (ICOM) towards widely-acceptable international standards of documentation.

(4) A recommendation will be sent to the Organising Committee of the International Botanical Congress, to be held in Leningrad in 1976, that EDP in taxonomic collections should be discussed and that consideration should be given to setting up a permanent International Commission to coordinate this.

(5) The working party will also consider systems and the possibility of establishing a pilot project in Europe.

(6) The working party will consider and advise on steps to form an international type-register.

(7) Relevant bodies should be encouraged to approach the appropriate United Nations agencies, particularly UNESCO and UNEP, to obtain funds for data banks on a national and international scale.

CELL MEMBRANE

Mobility of Surface Sites

from a Correspondent

MEMBRANE fluidity is certainly one of the most pervasive themes to have emerged in cell biology in recent years. The casual reader will be forgiven for believing that many cell biologists nowadays spend a considerable part of their time moving proteins around a sea of membrane lipid in a delightful molecular version of childhood pursuits. The carbohydrate binding proteins, for example concanavalin A which binds specifically to glucose or mannose-containing structures, are favourite probes for studying the mobility of molecules in the plane of the membrane. It is now widely believed that cell agglutination by con A results somehow from reorganisation of the cell surface to increase the ability of con A receptor sites to move together to form clusters and in the extreme case to 'cap' at one pole of the cell.

Tagging con A molecules with fluorescein allows application of a simple visual technique to the most sophisticated biological problems. A particularly interesting example has been described by Inbar, Ben-Bassat, Fibach and Sachs (*Proc. natn. Acad. Sci., U.S.A.*, **70**, 2577; 1973) who have found that the ability of mouse myeloid leukaemic cells to differentiate into phagocyte cells is related apparently to the fluid state of the surface membrane. Earlier work by Sachs and his colleagues had shown that normal undifferentiated haematopoietic cells transform *in vitro* into mature differentiated macrophages and granulocytes. Devel-

opment of macrophage and granulocyte colonies from single, normal undifferentiated cells requires constant interaction, presumably at the cell surface, with at least one specific mediator. The mediator is a protein with a molecular weight of about 65,000 that requires a small co-factor for activity (replaceable in certain conditions by adenine derivatives including cyclic AMP), and is released by various types of cells in culture into the tissue culture medium. The myeloid leukaemias contain two types of cells, only one of which can be induced to undergo normal differentiation. Again MG1 is needed but the leukaemic cells supply their own, as yet unidentified, co-factor. A clear difference between the two cell types was found by the ability only of the differentiation-competent cells to 'cap' con A molecules bound to their surface. In agreement with older results with normal lymphocytes, normal and virally transformed fibroblasts, clustering or 'cap' formation induced by cross-linking of membrane sites by con A was blocked by metabolic inhibitors, 'freezing' the membrane with aldehyde fixatives or simply by dropping the temperature. Again as often found in such cases, trypsinisation of differentiation-incompetent cells increased the mobility of con A binding sites and caps were formed.

Although thousands of similar observations have been described in a wide variety of systems, the molecular basis for increased mobility of surface sites is still obscure. A direct effect on the viscosity of the membrane lipids seems unlikely. The observation of Inbar *et al.* that 'cap' formation was helped by adding antibodies against con A, or of glycogen, after con A binding suggests that the surface sites were simply too widely spaced to form unaided the necessary cross-linked matrix with the lectin. Edelman *et al.* (*Proc. natn. Acad. Sci., U.S.A.*, **70**, 1442; 1973) suggest that the movement of surface sites is controlled by proteins attached to the inner cytoplasmic face of the surface membrane, the activity or concentration of which is altered. Certainly interaction between these internal proteins and external surface glycoproteins, that may span the cytoplasmic membrane, seems probable.

Whatever the true explanation turns out to be, however, the conclusion of Inbar *et al.* is that a difference in membrane fluidity of specific sites may explain differences in the ability of leukaemic cells to respond to the differentiation-inducing stimulus of MG1. It is now of some interest to correlate more directly the mobility of cellular MG1 receptor sites with the differentiation competence of those cells. Similarly one is curious about the behaviour of normally differentiation-incompetent

cells in an environment containing MG1 and low amounts of trypsin. Whatever the outcome there is no doubt that the experimental substance of this report will appear again and again in discussions of mechanisms controlling other facets of cell development.

INSECT METAMORPHOSIS

Competence to Moul

from our Insect Physiology Correspondent
It has long been known that when the 'imaginal disks' from young larvae of *Drosophila* are transplanted into larval hosts that are ready to pupate, they are unable to differentiate into adult structures. They gradually become competent for imaginal differentiation towards the end of the second instar, 50 to 70 h after hatching. The stimulus for the initiation of metamorphosis is a high concentration of the moulting hormone ecdysone.

In a short but interesting paper Mindek and Nöthiger (*J. Insect Physiol.*, **19**, 1711; 1973) describe a renewed attempt to discover the nature of the changes which result in the acquisition of competence. The experiments consisted in exposing eye-antennal disks removed from donor larvae 53 h old, which are completely incompetent for metamorphosis at this stage, and treating them in various ways before testing their competence by implantation into mature larvae, just before pupation at 120 h. Disks were maintained in adults receiving normal food, in adults 'starved' by feeding on sugar alone, or adults starved for a time and then given normal food. The results show that

competence to respond to ecdysone does not simply require a minimum number of cells (a 'critical mass'); nor is it determined by the time elapsed since the formation of the disk.

The authors conclude that cell divisions are the prerequisite for gaining new developmental possibilities and that a minimum number of cell divisions is needed to allow the necessary changes in the developmental programming of the cells.

PROTEIN SYNTHESIS

Control Mechanisms

from a Correspondent

EXPERIMENTS with mammalian cells in culture have revealed many diverse situations in which the rate of initiation of protein synthesis is greatly reduced. Besides the now classical example of rabbit reticulocytes deprived of haem, inhibition of initiation is seen when cells enter mitosis, are shifted to 42° C, starved of serum or an essential amino acid, infected with poliovirus or exposed to anaerobiosis. In some cases the inhibition is selective; more often the inhibition appears to affect all proteins to the same extent, but, apart from the inhibition of globin synthesis in the absence of haem, very little is known about the underlying control mechanisms. One reason for this is that extracts of cells other than the reticulocyte show almost no initiation on endogenous messenger RNA, so that normal and inhibited cells cannot easily be compared *in vitro*. This impasse has been present for a long time and only

Secondary Structure in an RNA Molecule

As soon as the primary structure of an RNA molecule is elucidated its discoverers set about the happy task of looking for possible secondary structures. When these are published they have tended to elicit alternative secondary structures from competing workers. How can a choice between these alternatives be made? The answer requires a means of assessing the free energy of a given structure and this in turn requires basic information concerning the free energy changes attendant on the formation of the various features—such as base pairs, hairpin loops, interior loops, bulges—which constitute the structure. Each new investigation of the thermodynamics of the secondary structure in oligonucleotides and other simple models leads to a refinement in these calculations.

In their latest paper Tinoco *et al.* (see *Nature New Biology* next Wednesday, November 14) amass recent results for

the sequence dependence of the free energy of formation of base pairs as well as that of various types of bulge and loop. The result is a table of free energy changes from which the total change on forming a given structure from the random coil state at 25° C can be calculated. Each entry in the table, it is claimed, is good to 10% but the uncertainty in the final figure may be somewhat greater; the authors also point out that the algorithm they describe does not take any account of tertiary structure. Nevertheless, it may serve to eliminate some of the more improbable models even if it does not allow a definitive assessment as to which is the most stable.

Tinoco *et al.* suggest that their work may lead to attempts to refine the theory and the experimental data on which it is based and even lead to investigation of temperature dependences which would be highly relevant to the interpretation of melting curves.

now, with a recent paper by Reichman and Penman (*Proc. natn. Acad. Sci., U.S.A.*, **70**, 2678; 1973), does it show any signs of being overcome.

Earlier work by Penman's group had shown that HeLa cells incubated at 42° C recover from the inhibition of initiation after 1–2 h. This recovery is prevented by actinomycin D, but not by cycloheximide, and, in fact, preincubation of cells at 37° C with low doses of this drug makes them less susceptible to inhibition of initiation at 42° C. These and other results suggested that when protein synthesis is slowed down, for example by high temperature, amino acid starvation or cycloheximide, the cells respond by making an RNA which promotes initiation. This RNA was predicted to have a half-life of about 1 h and to be rate-limiting for initiation in certain conditions.

When Reichman and Penman first tested extracts of normal HeLa cells for initiation *in vitro* they, like many others before, found very low activity, as measured by the pactamycin-sensitive incorporation of (³⁵S)-methionine into the N-terminal position of polysomal-bound nascent protein at 25° C. Bearing the earlier results in mind, however, they preincubated their cells for up to 4 h in the presence of a low concentration of cycloheximide and then prepared cell-free extracts, which showed up to six times more initiation. This increase in initiating capacity was prevented by preincubation with cycloheximide and actinomycin D, but was obtained when cells were preincubated in the absence of an essential amino acid. Developing the earlier model, Reichman and Penman suggest that the factor synthesised by intact cells in response to a reduction in protein synthesis is also the factor which is rate limiting for initiation in cell-free extracts, but they are somewhat more cautious in predicting that the factor is an RNA species. Although preliminary, these results open up exciting new possibilities for studying the control of initiation in mammalian cells.

PEAT

Origin of Palsa Mounds

from our Plant Ecology Correspondent

THE energy exchange properties of palsa mounds is the subject of a recent paper by Railton and Sparling (*Can. J. Bot.*, **51**, 1037; 1973), who provide a new approach towards understanding these mounds of peat with frozen cores which are abundant in the mires of high latitudes.

The word 'palsa' originated in Lapland and most of the research which has been undertaken on these features has come from Finland and the Soviet Union. In Finland palsas are only

found north of the coniferous forest limit in areas with a mean annual air temperature of –1° C and an annual precipitation of less than 400 mm. The palsas of that region are often irregularly shaped and may attain lengths of 200 m.

In the search for an explanation of the origin of these phenomena an initial question requiring solution is the start of their formation. By means of pollen analysis accompanied by radiocarbon dating, Salmi (*Proc. 3rd Int. Peat Congr., Quebec*, 182; 1968) came to the conclusion that palsas in Lapland fall into two groups, one of which began formation around 5000 BC and the other at about 3000 BC. The age of a palsa, however, did not seem to be related to its size. Other Finnish workers have found palsas of more recent origin and are less inclined to regard palsas as relics of past climates.

Railton and Sparling align themselves with those who believe in a continuous cycle of formation and erosion of the palsa mounds. They base this belief on their observation that all size classes of palsas are represented in their study area in northern Ontario and also that these classes exhibit a complete intergradation. They do not attempt to justify the assumption that palsa size is a function of palsa age, an assumption which appears rather tenuous in the light of Salmi's work.

They do, however, demonstrate some interesting relationships between palsa size and vegetation cover. Palsas containing a high percentage cover of *Sphagnum fuscum* were mainly less than 60 cm high and less than 7 m long. Lichen-rich communities with, for example, *Cladonia alpestris*, *C. floerkeana*, *C. rangiferina*, were found mainly on mounds greater than 60 cm in height. On the basis of these observations Railton and Sparling suggest that palsas develop continuously, and probably originate as *Sphagnum fuscum* hummocks on the mire surface. They become invaded and dominated by lichens during growth and finally erode and collapse. It is possible that the changes in heat exchange properties associated with the development of a lichen cover could account for the process of palsa development.

To test the feasibility of such a model Railton and Sparling measured the energy exchange properties of the different vegetation types. Total albedo was least on the general mire surface, increased in the *Sphagnum fuscum* hummocks, was greater still in hummocks dominated by lichens and reached a maximum in mature palsas. The obvious question which follows is whether these increases in albedo associated with palsa development are adequate to account for their negative heat budget and hence their growth. A

consideration of the total energy budgets of palsas led Railton and Sparling to the conclusion that the differences in albedo were not sufficiently great when compared with other energy exchange factors, and they are inclined to regard changes in the soil heat flux as being of greater importance. Thermal conductivity in peat decreases as the peat dries. Drier peat on the top of hummocks would lose heat less rapidly in summer, so helping to preserve the permafrost core. If this is so, then the lichen cover so often associated with mature palsas should be regarded as a product of mound development rather than a cause.

PLATE TECTONICS

Subduction Heating

from our Geomagnetism Correspondent

ACCORDING to the hypotheses of the new global tectonics, oceanic trenches, where colder oceanic lithosphere descends into the warmer underlying mantle, should be regions of relatively low surface heat flow; and this prediction is generally confirmed by observation. But observation also shows that behind oceanic trenches (that is, on the side of the trench opposite the spreading ocean floor) the heat flow is above average and associated with the volcanic island arcs. For some years after the basic principles of seafloor spreading and mantle convection had been mapped out, the causes of the volcanism and high heat flow, though clearly related in some way to global tectonic processes, remained obscure, and even today are far from being completely understood. In 1968, however, Oxburgh and Turcotte (*Nature*, **216**, 1041; 1968) and McKenzie and Sclater (*J. geophys. Res.*, **73**, 3173; 1968) made a significant advance by proposing independently that the origin of behind-trench phenomena lies in frictional heating on the slip zone between the descending lithospheric plate and the overlying mantle.

Such frictional heating certainly seems to be able to account for the surface observations behind oceanic trenches; and so several workers have attempted in various ways to calculate the subsurface temperature distribution in the descending plate. Turcotte and Oxburgh (*Phys. Earth planet. Inter.*, **1**, 381; 1968) and McKenzie (*Geophys. J.*, **18**, 1; 1969), for example, assumed in their calculations that the temperature is constant at the slip zone, whereas in later work McKenzie (*Tectonophysics*, **10**, 357; 1970) and Griggs (*The Nature of the Solid Earth*, McGraw-Hill; 1972) assumed the slip zone temperature to be equal to that of an undisturbed mantle. Then again, Oxburgh and Turcotte (*Bull. geol. Soc. Am.*, **81**, 1665; 1970) assumed that the

shear stress on the slip zone decreases with depth, whereas Minner and Toksöz (see, for example, *Tectonophysics*, **10**, 367; 1970) incorporated shear stress heating on both boundaries of the descending slab. But as Turcotte and Schubert (*J. geophys. Res.*, **78**, 5876; 1973) now point out, in these calculations little or no attention has been given to the positions of the volcanic chains behind ocean trenches—that is, to the geometry of the very system resulting from the thermal phenomena under investigation.

With the upsurge in geophysical activity during the past decade or so, many such volcanic chains have become quite familiar; and examples include the Kurile Islands, the West Indies, the Volcano and Mariana islands, Sumatra and Java, the Tonga and Kermadec islands and the New Hebrides. Turcotte and Schubert now propose that all these volcanoes lie above the points on the various slip zones where melting of the descending crust takes place. This assumes, of course, that the magma produced at the slip zone rises vertically to the surface, presumably under the buoyancy force arising from low magma density. Because the hydrostatic pressure is at least an order of magnitude greater than the ultimate strength of the rock at the depths of 100–200 km where the magma forms, the magma will probably move through the rock by the rock's plastic deformation rather than through a fracture; and in the absence of any other preferred direction, this movement will be vertically upwards. Accepting this geometry, the positions of the volcanoes may then be related to a specific process (melting) taking place on the slip zone and thus give an additional fixed point in calculating the subsurface temperature distribution.

Turcotte and Schubert develop two different models of heating on the slip zone. In the first, the shear stress along the slip zone is assumed to be constant down to the depth at which the basalt solidus temperature is reached; and thereafter the temperature at the slip zone remains at the basalt solidus (which increases with depth, of course). In the second model, the shear stress on the slip zone is allowed to increase linearly with depth to the point at which the solidus temperature is reached; and again, temperatures at greater depths are assumed fixed at the basalt solidus. Since the linearly increasing shear stress is equivalent to a constant coefficient of friction on the slip zone, the two models may be characterised, respectively, as 'constant shear stress' and 'constant friction'.

To cut a long physico-mathematical story short, what emerges from the Turcotte-Schubert analysis is an equation for each model which may be com-

pared with observation. In the case of the constant shear stress model, the operative equation gives shear stress in terms of the thermal properties of the system, its geometry (including the vertical distance from the volcanoes to the slip zone) and the velocity of the descending plate. Feeding in observational values for eight individual trenches gives shear stresses in the range 1.18–1.60 kbar, with a mean of 1.35 kbar and a standard deviation of 10%. For the constant friction model, the operative equation is for coefficient of friction in similar terms but with the addition of the mean density above the slip zone. Frictional coefficients calculated from observational parameters lie in the range 0.033–0.077, with a mean of 0.054 and a standard deviation of 24%.

In attempting to decide between the two models, these results are perhaps less clear than might have been hoped. Most of the volcano to slip zone distances lie between 100 and 120 km with errors in locating the slip zone estimated to be $\pm 20\%$. More variable distances would clearly have given a more convincing test for the constancy of either the shear stress or the frictional coefficient. Exceptionally, however, the volcano-slip zone distance for the New Hebrides system is 200 km; and the calculated shear stress at 1.31 kbar is much closer to the mean shear stress than the frictional coefficient of

0.033 is to the mean frictional coefficient. This, together with the smaller scatter of the shear stress values for the eight trench systems, leads Turcotte and Schubert to suggest that the constant shear stress model is probably the better of the two, although they are unwilling to commit themselves to a definite conclusion.

By extending their calculations to depths below the melting zone, Turcotte and Schubert go on to determine the thermal structure of the descending plate consistent with each model, on the assumption that the descending plate is largely olivine and thus that heating due to the olivine-spinel phase transformation, as well as adiabatic heating, is important. Other things being equal, the near-surface heating on the slip zone is somewhat stronger for constant shear stress than for constant friction, although for constant friction melting occurs at a slightly shallower depth. Apart from that, however, the temperature profiles are very similar. Finally, the temperatures on the slip zone are in fairly good agreement with those obtained by Toksöz *et al.* (*J. geophys. Res.*, **76**, 1113; 1971) but the minimum temperatures in the descending plate are about a factor of two lower. Turcotte and Schubert thus agree with others that the plate temperatures obtained by Toksöz *et al.* were probably too high, although the reason for the discrepancy is not clear.

Search for the Superheavies

ONE of the more interesting developments in nuclear physics recently has been the prediction by theorists of the existence of superheavy elements. This island of elements, with atomic numbers in the region of 114, lies significantly beyond the heaviest nuclei (numbers 104 and 105) which have so far been artificially produced and owes its possible existence to the extra binding energy and stability associated with the doubly closed nucleon shells at 114 protons and 184 neutrons.

Prediction of the half lives of these elements is particularly difficult, but some calculations have suggested values as long as 10^9 to 10^{15} years, implying that they might be found in natural materials on Earth. Several searches for superheavy elements in natural ores, minerals and so on have already been carried out and the results from one of the most complete are to be published in next Monday's *Nature Physical Science* (November 12).

The work has been carried out by a large group based on the Oak Ridge National Laboratory in Tennessee. The technique which they use relies on the prediction that superheavy elements are very likely to undergo spontaneous

fission and could emit an average of ten neutrons for each fission event; to be compared with values of less than four for presently known spontaneously fissioning nuclides. The neutron multiplicity counter they use records events in which either three, or more than three, neutrons are detected.

The technique has the advantage that bulky samples can be used and no chemical processing is necessary. Materials investigated range from mineral and ore samples, through flue dust and other samples collected during ore processing, to manganese modules and 60 million-year-old sharks' teeth from a depth of 15,000 foot in the Pacific Ocean and meteorites from Mexico.

In spite of this very wide range of samples no evidence was found for spontaneous fission events accompanied by large numbers of neutrons. It seems then unlikely that superheavy elements will be found naturally on Earth and that physicists will have to await attempts to produce them with the heavy ion accelerators now being planned and under construction. The search for the superheavies will no doubt continue.

LIQUID HELIUM

New Excitation

from our Condensed Matter Correspondent
A NEW type of elementary excitation, christened the ^3He roton, may exist in liquid ^3He - ^4He mixtures according to a calculation by Stephen of Rutgers University and Mittag of the University of Miami, published in a recent issue of *Physical Review Letters* (31, 923; 1973) and based on a suggestion made by L. P. Pitaevski during the United States-Soviet symposium on condensed matter at Berkeley in May.

Below its superfluid transition temperature T_λ , liquid ^4He can be regarded as an inert superfluid background in which exists a gas of elementary excitations carrying all the entropy of the liquid and thus being responsible for its thermodynamic properties. At zero temperature there are no excitations but, as T is increased, the density of the excitations, known as the normal fluid density (ρ_n), increases until at T_λ it is equal to the overall density of the whole liquid. In pure liquid ^4He , except very close to T_λ , there are two distinct types of elementary excitation: at small momenta, the energy ϵ of an excitation is directly proportional to its momentum p , and it is thus a phonon, or quantum of sound; at higher momenta there is a minimum in the $\epsilon(p)$ curve, and the excitations, all of energy close to Δ , existing in this region are known as rotons. Their physical nature is not entirely clear, but they may, perhaps, be the microscopic quantum mechanical analogue of classical vortex rings.

The addition of small proportions of ^3He profoundly affects the properties of the liquid. The ^4He atoms act as additional excitations, and thus increase the normal fluid density and contribute to the thermodynamic properties. Measurements of the heat capacity and wave velocity at very low temperatures have shown that a ^3He atom behaves very much like a free particle in that its energy varies as the square of its momentum, but with a modified mass m_3^* to take account of the superfluid background through which it moves.

When Sobolev and Esel'son made direct experimental measurements of ρ_n (*Zh. éksp. teor. Fiz.*, 60, 240; 1971) they found that ρ_n seemed to increase with ^3He concentration much more rapidly than expected. Since the contribution to ρ_n from the ^3He atoms is just $n_3 m_3^*$ where n_3 is their number density, and that from phonons at any given temperature depends only on the velocity of sound which does not change much with n_3 , it was concluded that the effect must be associated with a decrease in the roton energy Δ . Recent experimental measurements of Δ by Surko and Slusher of Bell Laboratories, and independently by Woerner, Rock-

well and Greytak of MIT, both using light scattering techniques and reported in the same issue of *Physical Review Letters* (30, 1111 and 1114; 1973) have shown, however, that Δ does not change significantly with ^3He concentration.

It was this apparent contradiction in the experimental evidence for the value of Δ which led Pitaevski to suggest that the $\epsilon(p)$ curve for ^3He excitations in liquid ^4He might also display a minimum, much like the roton minimum. If the value of ϵ at the minimum were less than Δ , then there would clearly be a possibility of resolving the conflict.

Stephen and Mittag have now carried out a detailed calculation, using the same theoretical approach as in the original Feynman-Cohen derivation of the $\epsilon(p)$ spectrum for pure ^4He . As Pitaevski had surmised, they find that the ^3He excitation spectrum does indeed display a minimum, that this occurs at an energy lower than Δ , and that it is thus possible to reconcile quantitatively, within-experimental error, the measured values of ρ_n with those of Δ . The probable reason that ^3He excitations near the minimum, referred to as ^3He rotons, were not also observed in the light scattering experiments is, the authors suggest, that the relative intensity of the scattering associated with rotons and ^3He rotons is proportional to the square of the ratio of the ^4He and ^3He number densities, so that, because the proportion of ^3He was always less than 30%, the former scattering process would have been strongly dominant.

Convincing confirmation that ^3He rotons really do exist, however, must probably await the results of further light scattering experiments.

CRYSTAL GROWTH

Crystallite Coalescence

from our Materials Science Correspondent
MASSON and his colleagues in Marseilles have published a series of beautifully executed electron microscope studies of the early stages of condensation of metallic films on ionic substrates; the strikingly novel finding from this work was that small crystallites can wander about in a two-dimensional walk, and, above a certain temperature, the migrating crystallites will coalesce when they touch by chance in the course of their wanderings. These findings have been summarised before (*Nature phys. Sci.*, 241, 1; 1973).

Now some theoretical implications of the Marseilles findings have been worked out by Robertson (*J. appl. Phys.*, 44, 3924; 1973) in a stimulating paper. He starts from the observation (by the Marseilles team and others) that whereas crystallites do in fact coalesce at elevated temperatures (for example, above

PHYTOPATHOLOGY

Find the Expert

Do you want to contact an expert on phyto bacteriology, or check the address of a rival mycoplasma fiend who may be duplicating your work? The problem may be solved by reference to the *World Directory of Plant Pathologists* (edited by Fran. E. Fisher). Perusal of this handy tome may reveal that a nematode expert last heard of in deepest Africa, or a virologist once dedicated to the study of wilt diseases in South American sugar beet, can be found in the quiet corner of a laboratory in Cincinnati or Birmingham, and a colleague who used to be satisfied with the epidemiology of avocado sun-blotch may have turned his mind to DNA.

Whatever they are doing now they can probably all be found out and tracked down in this directory. Within its covers 11,000 practitioners of the healing vegetable arts are listed under their countries of origin, together with address, telephone number and often details of professional interests. It is available (price \$12) from the editor at the University of Florida, IFAS, AREC, PO Box 1088, Lake Alfred, Florida 33850.

150° C in KCl), they do not at lower temperatures, although other evidence indicates that they do migrate at these lower temperatures. Robertson analyses the predicted coalescence kinetics in terms of migration rates and collision probabilities (which themselves depend on crystallite sizes). It turns out that there should be extensive coalescence under conditions when in fact none is experimentally observed.

Robertson speculates on possible reasons why collisions should not result in coalescence. Three ideas are put forward: the crystallites may in various ways pick up electrostatic charges or the substrate surface may be contaminated; either form of disturbance is known to inhibit coalescence of colloids suspended in fluids. The third source of disturbance, examined in more detail, is the buildup of misfit stresses between substrate and crystallites, and Robertson indicates that the possibly sharp dependence of misfit stress on crystallite size could lead to either enhancement or hindrance of coalescence. He concludes by claiming that the very process of crystallite migration is not yet established beyond all doubt, and that this is a research topic deserving of much more attention, since it may force a complete revision of the classical concept of heterogeneous nucleation and growth.

Irreversibility as a Symmetry-breaking Process

I. PRIGOGINE

Université Libre de Bruxelles, Brussels, Belgium, and Center for Statistical Mechanics and Thermodynamics, University of Texas at Austin, Texas

This article is based on the 1972 Bourke lectures of the Faraday Division of the Chemical Society.

It is just one hundred years ago that Boltzmann published his celebrated paper "Further Studies on Thermal Equilibrium between Gas Molecules"¹, in which he formulated his kinetic equation for the velocity distribution $f(\mathbf{v}, t)$ of dilute gases²

$$\partial f / \partial t = \int d\Omega \int d\mathbf{v} \sigma(\Omega) |\mathbf{v}_1 - \mathbf{v}| (f_1' f' - f f_1) \quad (1)$$

He then introduced the quantity $\mathcal{H}_B$ defined through

$$\mathcal{H}_B = \int d\mathbf{v} f \log f \quad (2)$$

and established as a consequence of equation (1) the inequality

$$d\mathcal{H}_B/dt \leq 0 \quad (3)$$

This basic inequality led him to the first microscopic model of entropy

$$S = -k\mathcal{H}_B \quad (4)$$

Boltzmann used physical intuitive arguments to obtain equation (1). He emphasized that the Second Law of Thermodynamics deals with large systems and that he therefore felt justified in adding to the laws of dynamics additional elements based on probability calculus.

Why are Boltzmann's investigations so central? They link together various levels of description of the physical world which had been introduced independently: classical or quantum dynamics, stochastic theory and thermodynamics.

Boltzmann's $\mathcal{H}$ theorem has led to a strange situation, perhaps unique in the history of science. On one side Boltzmann's kinetic equation has been applied successfully to many physical phenomena such as the calculation of transport properties of gases². More important still is the fact that computations based on molecular dynamics have entirely validated Boltzmann's predictions³⁻⁵. Such computer experiments show that indeed Boltzmann's quantity $\mathcal{H}_B$ decreases with time. (Because of the finite size of the sample, fluctuations appear but they decrease when the size of the sample is increased.)

These numerical experiments are very important, for they show that using only the laws of classical dynamics inequality (3) is satisfied for sufficiently large assemblies of interacting particles. In other words, the effects described by Boltzmann's kinetic equation (1) are in agreement with the results of numerical integrations based on classical dynamics. This gives one a strong incentive to investigate the conditions in which a dynamic system may present "dissipative" properties such as described by inequality (3), without introducing additional non-mechanical elements. I shall show that it is now possible to present a rigorous "mechanical theory" of irreversibility. Here I shall present only a very concise account of some of the chief ideas, omitting all proofs. More information can be found in refs 6, 7 and 8.

Time Reversal Symmetry

I shall start from classical or quantum dynamics as expressed by Hamilton's equations of motion

$$dq/dt = \partial H / \partial p \quad dp/dt = -\partial H / \partial q \quad (5)$$

or Schrödinger's equation

$$i\partial\psi/\partial t = H\psi \quad (6)$$

Both descriptions may be unified through the Liouville-von

Neumann equation for the distribution function (or the density matrix⁹)

$$i\partial\rho/\partial t = L\rho \quad (7)$$

with

$$L\rho = -i\{H, \rho\} \text{ Poisson bracket} \\ [H, \rho]_- \text{ commutator} \quad (8)$$

In both cases L is a hermitian operator (better called a super-operator because it acts on matrices in the quantum mechanical case, see refs 7 and 8). Therefore

$$L = L^\dagger \quad (9)$$

A basic feature of equation (7) is its " Lt invariance". Indeed, under the combined effect of the two operations

$$\begin{cases} L \rightarrow -L \\ t \rightarrow -t \end{cases} \quad (10)$$

equation (7) remains invariant. Note that if L is a possible Liouville operator so is $-L$. The " Lt invariance" expresses in a concise fashion the time reversal symmetry.

Now in spite of the " Lt invariance" some types of irreversible processes are still possible. For the example of a single particle enclosed in a large box the Hamiltonian is

$$H = p^2/2m \quad (11)$$

and equation (7) becomes

$$\partial\rho/\partial t + (\mathbf{p}/m) \cdot \partial\rho/\partial\mathbf{r} = 0 \quad (12)$$

In rather general conditions the density in coordinate space obtained from ρ through integration over the velocities, will become uniform in the box both for $t \rightarrow +\infty$ and for $t \rightarrow -\infty$ (see ref. 9, chapter 8). This is because the spectrum of the operator is continuous (see refs 9-12). Indeed, as can be easily verified (ref. 9, chapter 1) its eigenvalues are

$$\lambda = \mathbf{k} \cdot (\mathbf{1}/m)\mathbf{p} \quad (13)$$

where $\mathbf{k}$ is a real vector the value of which is determined by the boundary conditions.

Less trivial examples have also been considered. For example, one may study chains of harmonic oscillators and follow how equilibrium between kinetic and potential energy is achieved in the limit of large lattices¹³⁻¹⁸. In none of these cases, however, do quantities such as Boltzmann's collision operator or thermodynamic transport coefficients appear. This obviously requires stronger conditions than the continuous L spectrum. This conclusion may already be inferred from the structure of phenomenological equations such as the Fourier equation

$$\partial T / \partial t = \kappa \partial^2 T / \partial x^2 \quad (14)$$

As the heat conductivity κ is a positive quantity its sign cannot be reversed. Therefore the time inversion $t \rightarrow -t$ leads to the different equation

$$\partial T / \partial t = -\kappa \partial^2 T / \partial x^2 \quad (15)$$

This makes a pair of equations in each of which the direction of time plays a different role (in equation (14) the temperature becomes uniform for $t \rightarrow +\infty$, in equation (15) it was uniform for $t \rightarrow -\infty$); by contrast the single equation (12) predicts uniformity for distribution in coordinate space for both $t \rightarrow -\infty$ and $t \rightarrow +\infty$. The time reversal symmetry present in the dynamical description of equation (7) has been broken in equations (14) and (15).

One may say that the Second Law of Thermodynamics

$$dS/dt \geq 0 \quad (16)$$

summarizes in a single inequality all laws such as Fourier's law, friction phenomena and so on which are described by phenomenological equations involving a privileged direction of

time. This is the situation we associate with "thermodynamic irreversibility" and it is with this type of irreversibility that I am concerned here.

To return to the central problem: What are the conditions that have to be imposed on dynamics to obtain this behaviour? I believe that we can now give a precise answer to this question and show that the symmetry breaking is due to the possibility of analytical continuation for well defined dynamic quantities.

Dynamics and Dissipation

I shall first write the formal solution of the parabolic equation (7) in terms of the resolvent of the operator L (see ref. 9).

$$\rho(t) = \exp(-iLt)\rho(0) = (2\pi i)^{-1} \int dz \exp(-izt)(1/L - z)\rho(0) \quad (17)$$

The importance of this formal representation of $\rho(t)$ in terms of the resolvent comes from the fact that this representation incorporates causality (see refs 19 and 20). Indeed the contour c is a parallel to the real axis but has to be taken above or below it according to whether "retarded" solutions for $t \geq 0$ or "advanced" solutions for $t \leq 0$ are considered. The solution $\rho(t)$ is determined both by the differential equation (7) and the choice of the contour.

The formalism which I shall introduce now permits a discussion of the behaviour of the resolvent in the complex plane. The first step is to define orthogonal hermitian projection operators P, Q such that

$$P + Q = 1 \quad (18)$$

The choice of these operators fixes the "language" in which the results are formulated. I shall consider specific examples later. Generally P is chosen to project onto the diagonal elements in the representation in which some model Hamiltonian H_0 is diagonal (using here quantum mechanical notations)

$$\langle m | P \rho | n \rangle = \langle m | \rho | m \rangle \delta_{m,n} \quad (19)$$

As diagonal elements give no information about correlations between particles $P\rho$ is called the "vacuum of correlations".

Using P and Q it is easy to verify the following identity for the resolvent²¹⁻²³

$$\frac{1}{L - z} = \{P + \mathcal{G}(z)\} \frac{1}{PLP + \Psi(z) - z} \{P + \mathcal{D}(z)\} - \mathcal{D}(z) \quad (20)$$

with

$$\Psi(z) = -PLQ \frac{1}{QLQ - z} QLP \quad (21)$$

$$\mathcal{D}(z) = -PLQ \frac{1}{QLQ - z} \quad (22)$$

$$\mathcal{G}(z) = -\frac{1}{QLQ - z} QLP \quad (23)$$

$$\mathcal{D}(z) = -\frac{1}{QLQ - z} \quad (24)$$

These are the basic operators in the formulation of non-equilibrium statistical mechanics. Of special importance is the collision operator $\Psi(z)$: reading equation (21) from right to left it corresponds to a transition from the vacuum of correlations followed by a dynamical evolution in the correlation space and finally followed by a return to the vacuum of correlations. The operator $\mathcal{D}(z)$ corresponds to a transition $P \leftarrow Q$ and is therefore called the destruction (of correlations) operator, similarly $\mathcal{G}(z)$ is the creation (of correlations) operator. All these operators depend both on the dynamics of the system (through the Liouville operator L) and on the language used (through the projection operators P and Q).

The important point is that through the introduction of these operators one can study the limit for $z \rightarrow +i\epsilon$ and the analytic continuation of the resolvent (20).

Insertion of equation (20) into equation (17) leads to an integrodifferential equation for the retarded solution. This equation is generally called the "master equation"⁹ (for recent

applications see refs 24 and 25). Neglecting non-local and memory effects the master equation takes the simple form for the diagonal elements of the density matrix^{8,9}

$$i\partial\rho_0/\partial t = \Psi(0)\rho_0 \quad (25)$$

with

$$\Psi(0) = \lim_{z \rightarrow +i\epsilon} -PLQ \frac{1}{QLQ - z} QLP \quad (26)$$

(P has been chosen in such a way that PLP vanishes.) The collision operator has a specially simple physical meaning in the case of potential scattering. The matrix elements (in momentum representation) $\langle p | \Psi(0) | p' \rangle$ give then directly the scattering cross section for the transition $p \leftarrow p'$ (ref. 26).

In the limit of large systems, the sum over the intermediate states Q (the "correlations") involves an integration. Therefore a formal representation of equation (26) is given by²⁷

$$-i\Psi(0) = -\pi PLQ \delta(QLQ) QLP + iPLQ \frac{1}{QLQ} QLP \quad (27)$$

where the second term is understood as a principal part. If this formal expression is meaningful and each of the two terms exists, it follows that

(a) $-i\Psi(0)$ is split into an even and an odd part with respect to L inversion

$$\Psi(0) = \dot{\Psi}(0) + \ddot{\Psi}(0) \quad (28)$$

(b) the even part is a negative operator

$$-\dot{\Psi}(0) \leq 0 \quad (29)$$

(c) the even part $\dot{\Psi}(0)$ is hermitian while the odd part is anti-hermitian.

All these three properties are quite important. They solve in fact the three fundamental problems which have always faced non equilibrium statistical mechanics. First of all if the even part $\dot{\Psi}(0)$ exists, the master equation (25) obviously loses the Lt invariance. After Lt inversion one obtains

$$i\partial\rho_0/\partial t = [-\dot{\Psi}(0) + \ddot{\Psi}(0)]\rho_0 \quad (30)$$

This is precisely what would have resulted if in equation (17) the contour below the real axis had been taken and the "advanced" solutions constructed. The situation is quite similar to that discussed in the context of the Fourier equation (see equations (14) and (15)).

In the second place inequality (29) shows that the even part may be considered as expressing a "damping" which occurs in the future in equation (25) and in the past in equation (30) (for more details see ref. 6). Therefore inequality (29) contains in a nutshell the Second Law of Thermodynamics, equation (16). More precisely because of equation (29) a microscopic model of entropy can be constructed such that this entropy can only increase (or remain constant) for all initial value problem (see ref. 8 and I. P. and F. Henin, to be published). I shall come back to this question later.

Finally the third property (hermiticity of $\dot{\Psi}(0)$) permits it to be given, at least in simple cases, an interpretation in terms of transition probabilities in the sense of a Markoff chain^{8,28}. It is this property which leads from the initial dynamic description to a description in terms of stochastic processes.

One can see how deeply dynamics is altered when the collision operator $\Psi(0)$ does not vanish. The appearance of an even part in $\Psi(0)$ leads to a radical change in the dynamic description of the system. It should be noted that the discussion has been based on equation (25) rather than the general master equation. A general discussion will be presented later.

Dynamic Systems with Broken Symmetry

The basic importance of the even part $\dot{\Psi}(0)$ leads me to introduce the following classification: (a) $\dot{\Psi}(0)$ vanishes; this

is the situation for quantum systems with a discrete non-degenerate spectrum (then $z=0$ in equation (26) does not belong to the spectrum of QLQ); (b) $\Psi(z)$ becomes undefined when the limiting process $z \rightarrow +i\epsilon$ is performed. This may be the case for quantum system with discrete but degenerate spectrum (for examples see refs 29 and 30). This situation also occurs in classical dynamics when gravitational forces are involved^{31,32}; (c) finally, there is the situation in which $-i\Psi(0)$ is well defined and negative

$$-i\Psi(0) \leq 0 \quad (31)$$

This is the dynamic dissipativity condition. (This terminology agrees with the common mathematical terminology³³.) When satisfied it implies a qualitative change in the structure of the invariants of the system and it is a necessary condition for a thermodynamic type of behaviour. As already noted, inequality (31) cannot occur unless the spectrum of L is continuous. At least for quantum systems this is only possible in the limit of an infinite volume and eventually also of an infinite number of particles (the so-called thermodynamic limit).

For scattering these three cases correspond, respectively, to the situations where the S matrix is unity (no scattering), where the scattering cross section diverges and finally to the situation where the cross section is different from zero, when it is necessarily positive. The dissipativity condition also applies, however, to much more general situations. Examples of N body dissipative systems have long been known⁹. The operator $\Psi(0)$ has been calculated explicitly for systems such as weakly coupled gases or slightly anharmonic solids. In all these cases it is easy to verify that in accordance with our general statement $-i\Psi(0)$ has an even part, is negative and hermitian. For such systems the dissipativity condition has a very simple meaning—that there are processes which conserve energy and momentum such that the integral involved in $\Psi(0)$ (see equation (17) and remarks earlier in this article) does not vanish. This was discussed in detail some years ago (see ref. 9, chapter 14). This interpretation applies, however, only to very simple situations.

The construction of $i\Psi(0)$ may be extended to strongly coupled system using formal perturbation techniques⁸. It is also very instructive to study simple models where a rigorous, non-perturbative approach is possible.

A simple example is given by the Hamiltonian

$$H = \sum_{m,n=-N}^N |m\rangle H_{m,n} \langle n| \quad (32)$$

where $H_{m,n}$ is a hermitian, Toeplitz form characterized by the properties

$$H_{m,n}^N = H_{m-n}^N \quad (33)$$

These systems have recently been studied carefully by Gibberd and Stey, Stey^{29,30} and Grecos³⁴. In the limit $N \rightarrow \infty$ they satisfy rigorously the dissipativity condition (31).

A second example is Friedrichs's model^{28,35-39}. The Hamiltonian is then of the form

$$H = H_0 + \lambda V \quad (34)$$

where H_0 has a continuous spectrum and an embedded discrete eigenvalue ω_0 coupled through the λV perturbation.

The Friedrichs model is related to various models investigated in the literature such as the Wigner-Weisskopf model for a two-level atom, the Lee model in field theory and so on.

As in the case of the Toeplitz forms, the Friedrichs model is soluble, as the transformation which diagonalizes H can be obtained. Because of the continuous nature of the spectrum, H will admit in general both eigenfunctions and eigendistributions (containing δ functions as well as principal parts).

We may choose³⁶ P so that $P\rho$ is the probability of finding the unstable (discrete) state excited at time t . Here again the resolvent of the von Neumann operator as well as $\Psi(z)$ can be obtained by a direct calculation using equations (20) and

(21). It turns out that

$$\Psi(0) = \dot{\Psi}(0) = \left[-\frac{1}{2i\pi} \int_{-\infty}^{+\infty} dx \eta^+(x) \eta^-(x) \right]^{-1} \quad (35)$$

Here $\eta^\pm$ are the limiting values on the real axis of the analytic function

$$\eta(z) = \omega_0 - z - \lambda^2 \int_0^\infty d\omega |\nu(\omega)|^2 / (\omega - z) \quad (36)$$

I assume that the continuous spectrum of H_0 and thus of H extends over the positive real axis; $\nu(\omega)$ measures the coupling between ω_0 and the continuous spectrum.

Because in this case P is a one-dimensional projection, $\Psi(0)$ as given by equation (35) is a number (while in the Toeplitz case Ψ is an operator represented by a matrix).

Using equation (36) we have shown³⁶ that $\dot{\Psi}$ does not vanish if the coupling parameter λ is smaller than a critical value, a condition which implies that H has no point spectrum corresponding to a bound state; $i\Psi$ is essentially the inverse of the life time of the unstable state. These examples establish rigorously the existence of dynamic systems with broken Lt symmetry.

Invariants of Motion and Dissipation

One has to expect a close connexion between the non-vanishing of the collision operator $\Psi(0)$ and the problem of the invariants of motion.

I shall consider a Hamiltonian H together with the projection operator P (see equation (18)) and write

$$H = PH + QH = H_0 + \lambda V \quad (37)$$

This relation defines the "unperturbed" Hamiltonian H_0 . Now suppose that the problem of invariants for PH has been solved; every observable $P\Phi$ commutes with PH and is an invariant of motion. The basic problem will be to study the possible relation between the invariants of H and of PH . Now suppose that Φ is an invariant for the dynamical system. Then

$$L\Phi = 0 \quad (38)$$

The invariants Φ may be classified into regular or singular^{36,37,40}. (Briefly, singular invariants are such that their off-diagonal part $Q\Phi$ does not satisfy the regularity conditions necessary to include it in a Cauchy integral). If both the collision operator $\Psi(z)$ and the creation operator $\mathcal{C}(z)$ (see equation (23)) exist in the limit $z \rightarrow +i\epsilon$, then starting from equation (38) a few manipulations show that regular invariants satisfy the conditions^{36,40,42}

$$\Psi(0)P\Phi = 0 \quad (39)$$

$$Q\Phi = \mathcal{C}(0)P\Phi \quad (40)$$

showing the essential importance of the collision operator. If it were to vanish the result would simply be

$$Q\Phi = \mathcal{C}(0)P\Phi \quad (41)$$

To each invariant Φ_0 of PH , then, corresponds the invariant Φ_0 , $\mathcal{C}(0)\Phi_0$ of H . If, however, $\Psi(0)$ does not vanish then the conditions for regular invariants (39) and (40) are much more restrictive as $P\Phi$ has then to be an eigenfunction of the collision operator corresponding to a zero eigenvalue. Obviously this destroys the one-to-one correspondence between the invariants of PH and the regular invariants of H .

For example, in the Friedrichs model, H has lost the discrete eigenvalue of PH in the dissipative case. The complete set of invariants of H has been calculated and it has been verified that in the dissipative case there exists no regular invariant^{36,40}.

Although dissipativity implies the breaking of the one-to-one correspondence between the invariants of PH and of H , the inverse is not true. Poincaré's work^{9,43} provides simple examples of finite classical systems in which H admits no trivial invariants which are analytical in the coupling constant.

Nonetheless it is easy to show that in these cases the limit (26) does not exist because of the finiteness of the system. The breaking of the correspondence between the invariants of PH and of H is therefore a necessary but not a sufficient condition for dissipativity.

Causal Dynamics

The chief conclusion of my approach here is that dissipative properties correspond to a breaking of the Lt symmetry. This symmetry breaking was, however, obtained through the study of the integral representation (17) which as we have mentioned, includes causality. I shall now establish a differential equation of motion which exhibits explicitly this symmetry breaking and would therefore be the natural generalization of equation (25) valid only for simple situations (such as corresponding to weakly coupled systems). This can indeed be done in terms of a new extended formulation of transformation theory (see refs 8, 28 and 38) and, especially, ref. 44.

To summarize the basic ideas: we may ask what is the relation between the original Liouville equation (7) or its integral representation (17) and an equation such as (25) which contains both odd and even terms. The point of view as developed by our group is that both equations are exact representations of the dynamic evolution of the system. This equivalence should therefore be expressible in terms of a transformation theory which would lead from equation (7) to a new equation

$$i\partial\rho/\partial t = \Phi\rho \quad (42)$$

where the evolution operator Φ would, for dissipative systems, also contain an even part in respect of L .

In other words, one has to consider a relation of the form

$$\rho = \Lambda(L)\rho \quad (43)$$

where the transformation operator Λ depends on L . Indeed substitution of equation (43) into equation (7) yields

$$\Phi = \Lambda^{-1}L\Lambda \quad (44)$$

As both representations (7) and (42) are considered equivalent the transformation Λ should preserve average values of observables, that is, it must be such that

$$\langle O \rangle_t = \text{tr} O^+ \rho(t) = \text{tr} O^+ \rho \quad (45)$$

with

$$O = \Lambda(-L)O \quad (46)$$

$\Lambda(-L)$ has to be used in equation (46) because the evolution operator for observables is, in the Heisenberg scheme $-L$ (and not $+L$ as in the Liouville equation). Moreover the transformation has to preserve the hermitian character of the observables and the density matrix.

An important feature of these transformations is that they are non-unitary but satisfy the condition

$$\Lambda^{-1}(L) = \Lambda^+(-L) \quad (47)$$

It is only for transformations independent of L (or even in L) that one comes back to unitary transformations, but then Φ in equation (44) could not contain both even and odd terms in L . This new class of transformations has been called "starunitary" transforms. It is easily shown that equation (47) leads to the invariance of average values as expressed in equation (45). The generator of time displacement Φ can be viewed as an extension of the collision operator $\Psi(0)$ introduced earlier.

The three basic properties of $\Psi(0)$ discussed earlier are shared by the operator Φ (refs 8, 38 and 45). We may again split Φ into an odd and an even part in respect to L inversion. Equation (42) is valid for the retarded solution. The advanced solution would satisfy an equation similar to (30) in which the sign of the even part Φ is reversed. Therefore causality is explicitly included in this formulation of dynamics. For this reason we have called equation (42) the "causal" formulation of dynamics.

As $-i\Phi$ is a seminegative operator the evolution of dissipative systems may be described in terms of a Liapounoff function. I shall indeed consider the quadratic functional in the causal representation (dropping the superscript ϕ)

$$\Omega = \text{tr } \rho^+ \rho \quad (48)$$

It is easy to show using equation (42) that

$$1/2 \, d\Omega/dt = -\text{tr } \rho^+ (i\Phi) \rho \leq 0 \quad (49)$$

The property (49) implies that the statistical equilibrium corresponding to a minimum of Ω has a very simple meaning in the causal formulation of dynamics: all quantum states have the same probability and random phases.

We may now introduce the quantity $\mathcal{H}$ defined through

$$\mathcal{H} - \mathcal{H}_{\text{eq}} = 1/2 \log (\text{tr } \rho^+ \rho / (\text{tr } \rho^+ \rho)_{\text{eq}}) \quad (50)$$

This corresponds then to a microscopic model of entropy given by

$$S = -k\mathcal{H} \quad (51)$$

Notice that

$$\begin{aligned} \mathcal{H} - \mathcal{H}_{\text{eq}} &\geq 0 \\ d\mathcal{H}/dt &\leq 0 \end{aligned} \quad (52)$$

$\mathcal{H}$ is an additive function for independent systems.

I cannot enter here into a detailed discussion of our quantity $\mathcal{H}$ (50) which gives, in my opinion, the general dynamic interpretation of the Second Law of Thermodynamics (16) (see I. P. and F. Henin, to be published). Briefly, however, the quantity $\mathcal{H}$ (50) corresponds to the approach of the system to microcanonical equilibrium. It can only decrease in time whatever the initial conditions (at least when some regularity conditions are satisfied³⁶). This is a basic difference with Boltzmann's definition (2) which even for dilute gases requires initial conditions compatible with the validity of the kinetic equation (1).

Irreversibility is a dynamic property based on the possibility to subdivide the solutions of the equation of motion into two semigroups corresponding respectively to retarded and advanced solutions. Entropy increases with time for each retarded solution.

Note that because the entropy is a non-linear functional of the density matrix it cannot in general be expressed in terms of observables such as temperature and density. This is only possible in the neighbourhood of equilibrium (ref. 46 and I. P. and F. Henin, to be published). It is only then that both entropy and entropy production acquire a macroscopic meaning. Briefly, the Second Law of Thermodynamics becomes a theorem in dynamics which only near equilibrium can be expressed in terms of macroscopic variables.

I shall finally compare the causal representation to the representation in which the Hamiltonian is diagonal. In such a representation one would have non-interacting excitations. Now obviously in the interaction of systems with continuous spectrum two quite different effects have to be taken into account: a modification of the interacting units ("renormalization") and an overall effect of a thermodynamic nature which expresses that the interaction permits to the system to approach equilibrium. This thermodynamic aspect of interaction has already been emphasized in the classical Einstein work on the interaction of matter with radiation⁷. The star unitarity transformation permits to treat both effects of the interaction. For non-dissipative systems one returns to the usual unitary transformation in which the only effect of the interaction terms is to redefine the excitations.

These problems will be treated more completely elsewhere (see I. P., C. George, A. Grecos and F. Henin, to be published).

Dissipative Structures

I shall now make some remarks pertaining to macroscopic thermodynamics. Once an entropy can be associated with the dynamic evolution of a system it is possible to distinguish between near and far from equilibrium situations.

This leads precisely to a distinction between "equilibrium structures"⁴⁸ which may be understood in terms of classical equilibrium thermodynamics and "dissipative structures". The latter are formed and maintained through the exchange of energy and matter in non-equilibrium conditions. Many examples of dissipative structures in fluid dynamics or non-linear chemical networks are now known. Their formation always requires a minimum distance from thermodynamic equilibrium and their appearance expresses the fact that the "thermodynamic branch", which corresponds to the extrapolation of equilibrium to non-equilibrium situations, becomes unstable against fluctuations.

Of special interest are symmetry-breaking dissipative structures in which the system has the "choice" between various possibilities. The type of initial fluctuations determines the specific dissipative structures which will be realized. Once realized this dissipative structure is stable against the type of fluctuations considered. Successions of instabilities of this type may occur, involving a kind of primitive memory or, so to say, a "historical dimension"^{48,49}. The present structure of the system can only be understood in terms of the succession of instabilities through which it originated.

There seems to be little doubt that there is a close connexion between dissipative structures and biological organization. For example, important biological multi-enzymatic processes have been shown to work beyond the stability limit of the thermodynamic branch. More details may be found in ref. 49. These considerations have to be borne in mind when the problem of the origin of irreversibility is discussed.

I shall conclude this article with some epistemological considerations about the origin of irreversibility. (For more details see refs 50-52.)

The Second Law of Thermodynamics has been repeatedly considered as the basis for the introduction of the concept of irreversibility. Others, on the other hand, base their explanations of irreversibility on biological functions such as memory. My approach leads to a model which incorporates both ideas.

To obtain the dissipativity condition (31) it was necessary to start with the formal solution (17) which as already emphasized, includes causality. Once condition (31) is satisfied, all retarded solutions lead to an increase of entropy in time. Now the incorporation of causality means that the future can at the outset be distinguished from the past. Then, using the laws of mechanics and, specifically, the dissipativity condition, one derives for such systems the existence of a thermodynamic description. In the framework of this description the concept of dissipative structures with their possible time anisotropy may be defined as in the previous section. This sequence may be expressed graphically⁵⁰⁻⁵² as in Fig. 1. Without the distinction between future and past, entropy could not be introduced, but without entropy dissipative structures in which the distinction between past and future is, so to speak, built in, could not be obtained. If we wish we may consider ourselves as a specific dissipative structure. This interpretation of irreversibility means then that we recognize in the outside world classes of objects which have precisely the property (anisotropy of time) which we have attributed to ourselves at the start.

The concept of irreversibility, and especially the Second Law of Thermodynamics, plays an important role in many parts of theoretical physics. Our unified formulation of

dynamics and thermodynamics is therefore likely to open new perspectives for theoretical research.

This article summarizes some aspects of work done by our groups in Brussels and Austin. I thank my colleagues and friends M. de Haan, Cl. George, A. Grecos, F. Henin, F. Mayné, G. Nicolis, L. Rosenfeld and G. Stey for elaboration of the ideas summarized here. This work has been supported by the Welch Foundation, Houston, and the Fonds de la Recherche Fondamentale Collective, Belgium.

On June 30, 1973, Concorde 001 intercepted the path of a solar eclipse over North Africa. Flying at Mach 2.05 the aircraft provided seven observers from France, Britain and the United States with 74 min of totality bounded by extended second (7 min) and third (12 min) contacts. The former permitted searches for time variations of much longer period than previously possible and the latter provided an opportunity for chromospheric observations of improved height resolution. The altitude, which varied between 16,200 and 17,700 m, freed the observations from the usual weather problems and greatly reduced atmospheric absorption and sky noise in regions of the infrared.

THE Concorde took off from Las Palmas in the Canaries, intercepted the eclipse over Mauritania, paced the umbra along a great circle path over Mali, Algeria, Niger and part of Tchad, and landed in Fort Lamy. The astronomical requirement of stable flight throughout both a maximum period of totality and the second and third contacts (natural contacts) imposed a rigid schedule on the Concorde. Had the aircraft been 2 min early on arrival in the eclipse path, the period of totality would have been reduced by 25 min and one natural contact would have been lost. On the day of the eclipse the Concorde took off and intercepted the umbra within 5 s of the allotted times after 45 min of flight; it maintained maximum ground speed (544 m s^{-1}) (Mach 2.00 to 2.10) throughout the observations and the duration of totality was determined by meteorological conditions in the stratosphere. (We note that the exact definition of second and third contact may have to be re-examined when

the transit of the Moon is very slow.) There was no interference with ground sites and observers. All this is a magnificent achievement on which we congratulate Captain Turcat and his crew.

Fig. 1 A view of the aircraft, showing the four special purpose windows on the top. From front to back: crystal quartz window, composite Irtran-2 window, two fused quartz windows. (Picture by Aérospatiale.)

The Concorde carried equipment for experiments by five groups. The instruments and their performance are discussed in the following sections. Apart from four window assemblies, which were mounted in the roof (see Fig. 1), the aircraft required no structural modifications as the equipment was attached to the standard floor tracks. The limitations on space and weight were not severe. The Concorde was made available for five test flights before the eclipse including three Sun-tracking flights. During the eclipse itself the stability of the aircraft was excellent: pitch $\leq 0.1^\circ$, roll $\leq 0.5^\circ$ (peak-to-peak values). An unusual

problem was that, during the eclipse, the attitude of the Sun varied from 27° below zenith ahead of the aircraft to nearly overhead and then to 23° below zenith behind the aircraft.

Here we describe the five experiments, going from the front to the back of the aircraft's cabin.

Far Infrared Emission from the Chromosphere

The purpose of this experiment (Queen Mary College, London) was to examine the upper chromosphere using its emission between $300\ \mu\text{m}$ and $1,500\ \mu\text{m}$. An eclipse gives a necessary condition for this observation, for only lunar occultation of successive layers can produce the required angular resolutions, of order 1 arc s. The best that can be done outside eclipse is around 40 arc s using a large telescope such as the 36-foot NRAO dish at Kitt Peak, because of diffraction limitations. Further, the effective slowing down of the Moon's passage by a factor of ten, enables a high enough signal to noise ratio to be obtained to use the angular resolution available. A final advantage of using the Concorde was that at heights of over 50,000 foot, well above the tropopause, radiation between $300\ \mu\text{m}$ and $1,000\ \mu\text{m}$ reaches the equipment almost unaffected by absorption due to the water vapour rotational spectrum. At ground sites, the average transmission in this wavelength range is only a few per cent.

Our equipment comprises a Rollin InSb photoconductive detector, cooled to liquid He temperature, with useful detectivity between $250\ \mu\text{m}$ and 2 mm. This was fed by a conventional Michelson spectral interferometer, having a $50\ \mu\text{m}$ thick melinex beamsplitter, and 6-cm diameter plane reflectors. The interferometer could be switched to scan through a path difference of 2 cm in 1 s, giving audio output frequencies between 10 Hz and 80 Hz, or ten times more slowly. In the former case analogue Fourier transformation could be performed with suitable electrical filter networks; in the latter digital transformation is needed, to obtain the spectrum of the radiation. The interferometer was fed by an image of the whole eclipsed disk, through a chopper at 1 kHz, used in conjunction with a phase sensitive detector at the output of the radiation detector. Optically the system was very simple: the solar beam passed through the aircraft window, a disk of single crystal quartz, 12 cm in diameter chosen for its transmission properties. It was folded with several plane mirrors on to a lens of TPX plastic, also of high far infrared transmission, into the interferometer. One of the plane mirrors had to be moved electrically at a pre-calculated nearly linear rate along the aircraft axis during totality. A second was guided about the roll axis electrically, using a servo circuit linked to the inertial navigation system of the aircraft, and about the pitch axis manually. A small optical telescope aided the guiding, fed by a 2-cm flat, through which the observer could see the eclipse and surrounding coronal light. Invaluable help was given in designing and constructing the equipment by the National Physical Laboratory Electrical Science division, by the Science Research Council's Culham Laboratory, and particularly by the Radio and Space Research Station, Slough.

The experiment can be counted a success, in that all the individual systems worked, and data were obtained on chart and magnetic tape. Preliminary analysis of the data is consistent with emission detected from the chromosphere, of the right intensity compared with the lunar far infrared signal, and covering the correct angular range outside the lunar disk. The chromospheric signal seems to have been detected not only during the 7 min before photospheric second contact (onset of totality) and 12 min after third contact, but for some 5 min after second and before third contacts.

Infrared Emission of the Thermal Corona

The aim of this experiment (Observatoire de Meudon) was to assess the emission of the thermal corona, or dust corona, in the wavelength range 2 to $13\ \mu\text{m}$. The main advantages of mounting it onboard Concorde are: (i) better atmospheric transmission at 17,000 m; (ii) correspondingly reduced fluctuations of the atmospheric emission which seem to have hampered ground observations at the 1970 Mexican eclipse; (iii) longer integration time.

The window assembly consisted of a circle of four Irtran-2 disks, each of clear diameter 10 cm, with a 3-cm fused quartz window at the centre for guiding purposes. All the optics were mounted on a sliding table, shock-mounted to the floor, to follow, without vignetting, the apparent motion of the Sun in the aircraft. A gyro-heliostat, provided by NASA, stabilised the image on an off-axis, 50 cm diameter, $f/3$ telescope. Image acquisition and scanning were achieved manually by visual control of the image in the focal plane. Differential modulation in this plane switched two diaphragms, 4.4 arc min in diameter, 22 arc min apart in order to balance instrument emission. The beam was divided into three measurement channels, covering respectively 2 to $3\ \mu\text{m}$, 4 to $5\ \mu\text{m}$, 8 to $13\ \mu\text{m}$. The detectors were respectively liquid N_2 cooled InSb photoconductors and liquid He cooled Ge-bolometer.

All three channels could be operated either wide band, or with spectral resolution of about 50 provided by a grating or by a filter wheel (8 to $13\ \mu\text{m}$ channel). Data, including various parameters on board, were recorded both in analogue and in digital form. Total weight of the experiment was about 400 kg.

All the subsystems performed properly during the flight, and the Moon+corona acquisition proved easy. Tracking stability stayed better than 1 arc min for most of the flight. Fifty-six minutes were devoted to wide band scans along and perpendicular to the ecliptic, from 3 to 8 solar radii. Eighteen minutes were devoted to spectral scans at 3.9 solar radii (the area of maximum emission at $10\ \mu\text{m}$).

The radial scans should allow confirmation of previous results at shorter wavelengths, to correlate the longer wavelength emission with them, and hopefully to throw some light on particles material identification through their emission spectra in the $10\ \mu\text{m}$ band.

Invaluable help in building the equipment was provided by the Laboratoire de Physique Stellaire et Planétaire and the Services des Prototypes, both CNRS Institutes, by the Centre National d'Etude des Télécommunications and by Kitt Peak National Observatory.

Photographic Study of the Corona

The experiment (Institut d'Astrophysique de CNRS, Paris) aimed to measure the lifetime of typical structures in the inner corona ($r < 1.5 R_\odot$), to search for oscillatory motions, and to study the outer corona ($r < 15 R_\odot$), by photographic photometry. Three cameras were mounted on a manually oriented gimbal, observing through a fused quartz window 135 mm in diameter. Respective focal lengths are: 180 mm, 1,520 mm, 3,000 mm. Kodak Recording 247S, TRI-X-P and Ektachrome EF films were used. Results on the three systems are as follows.

(1) Several photographs at wide field exposed at 1/30 and 1/60 s; sky brightness appears very low at 17,000 m and should allow a study of the corona at large distances.

(2) Thirty-seven photographs $60 \times 60\ \text{mm}$, 2 min apart, on the 3 m camera, 1/60 s exposure; resolution is of the order of 2 arc s. (Some of these are shown in Fig. 2.)

(3) Two hundred and thirty colour photographs (24×36 format), on the 1.5 m camera. The black and white photographs are calibrated.

Structural changes in the corona are noticeable at the poles, as well as in a coronal enhancement on the eastern side. Photometric study of the films should allow a determination of the lifetime of the polar plumes and an investigation of relaxation processes in the inner corona. Propagation of a coronal wave at the W limb and at about $1 R_{\odot}$ from the limb may be studied. The high spatial resolution should allow investigation of the effect of a supersonic shock wave on the wave front, and thus on the image quality.

High Resolution of the Emission Line Corona

These observations (University of California, Los Alamos Scientific Laboratory, Los Alamos) had two purposes; (1) to determine whether the mechanical periodicities of 5 min observed in the photosphere contribute to the heating of the corona; (2) to use the slow motion shuttering of the solar atmosphere by the lunar limb to observe the development of the emission corona just above the chromosphere.

If the corona-chromosphere transition is about 1,000 km thick, this latter observation would be completed in about 3 s for an observer at a ground site while on Concorde about 30 s were available.

Fig. 2 Successive photographs of the solar corona, taken with $f=3$ m every 20 s, exposure 1/60 s. (J. Begot, Institut d'Astrophysique.)

A single 10-cm fused silica window was left uncoated because of the large altitude change of the Sun during totality. Close to this window a two-axis mirror was located to direct the light into a telescope of aperture 7.6 cm and focal length 1 m. The mirror was guided from photoelectric error signals produced on a tracking focal plane by splitting off 10% of the light from the main beam. The long focal length and consequent large f number was used to obtain a good image scale so that resolution to 10 arc s was available. The main beam was recollimated and passed through an interference filter with a square pass band about $9 \text{ \AA}$ full width at half intensity points. Then spectral scanning through the $\lambda 5303$ emission line was accomplished with a pressure scanned Fabry-Perot interferometer. The image was reformed without change in magnification onto the image intensifier surface optically linked to the vidicon tube. A video frame was obtained every 20 ms and the interferometer finesse, about 50, and scan rate, were adjusted to give 0.5 mm ($0.05 \text{ \AA}$) resolution. Digitisation and subsequent analysis as previously used will be accomplished at Los Alamos. This detailed spectral study was complementary to the successful observations in other coronal emission lines carried out by

other Los Alamos scientists on the NC-135 that was passed by the Concorde near the mid-eclipse point. The instrument weighed about 250 kg.

The main objectives of the observations were achieved. Good spectral line profiles were obtained, and the relative intensity calibration on the video recording will give reliable detection of periodic intensity changes. Although some tracking difficulties were encountered with the photoelectric tracker during the eclipse, adequate tracking was obtained during totality and around third contact to give emission line profiles for both the above purposes.

Particularly striking to the observer was the very dark sky on which a brilliant blue white corona was superposed like a cameo. Near third contact the emergence of the red (hydrogen line-emitting) chromosphere was particularly beautiful as the chromospheric crescent protruded from behind the lunar limb and spread around about a quarter of the solar circumference before the photosphere emerged to end totality. Of course the corona could be seen well after third contact and up to the time we turned away to land at Ft Lamy.

Near Infrared Emission of the Upper Atmosphere

A two-channel spectrophotometer (University of Aberdeen) was used to study the infrared atmospheric system of molecular oxygen in emission. Interference filters with peak transmissions close to $1.27 \mu\text{m}$ and $1.58 \mu\text{m}$ were tilted by motor-driven cams to give spectral scans approximately $0.04 \mu\text{m}$ in range every 60 s. The widths of the passbands of the filter were $0.007 \mu\text{m}$ and $0.01 \mu\text{m}$ respectively. The spectrophotometer was placed close to a passenger window towards the rear of the fuselage in a mounting that permitted selection of the elevation angle of the field of view between 0° (horizontal) and 40° .

The regular dayglow at $1.27 \mu\text{m}$ and $1.58 \mu\text{m}$ was observed during all flights and good measurements of the $1.27 \mu\text{m}$ emission were obtained throughout the total eclipse. The $1.58 \mu\text{m}$ emission disappeared into noise before third contact but was seen clearly before second contact. Observations were obtained at a number of differing elevation angles during totality as well as during the test flights and it is clear that the data will yield estimates of (a) the intensities of the two emission radiances and their ratio; (b) the effective atmospheric absorption of the $1.27 \mu\text{m}$ emission; (c) the effective quenching rate for the $^1\Delta_g$ excited level of O_2 ; (d) the variation with latitude of the $1.27 \mu\text{m}$ emission radiance; and (e) the lack of medium-scale irregularities in the dayglow radiance.

The full results of the individual experiments will be published by the various participating groups; but it is already worth pointing out how profound a change in eclipse observations has accompanied the advent of supersonic aircraft, which has proved to be a very successful carrier in this particular project. There can be no doubt that future plans should favour this method over more conventional approaches.

The project was made possible through the French Délégation Générale à la Recherche Scientifique et Technique and was coordinated by the Institut National d'Astronomie et de Géophysique of the Centre Nationale de la Recherche Scientifique with the full support of the Aerospatiale Company. French experiments were supported by the Institut National d'Astronomie et de Géophysique, British experiments were supported by the Science Research Council and the United States experiment by the National Science Foundation.

Mr Ravaut provided invaluable help during all the flights.

Received October 3, 1973.

Geomorphological Dating of Cave Openings at Makapansgat, Sterkfontein, Swartkrans and Taung

T. C. PARTRIDGE

PO Box 31023, Braamfontein, Transvaal

Cave opening at several of the South African hominid sites occurred through incision and valley widening in one current erosion cycle. Measurements of rates of cyclic nickpoint migration and valley flank recession make possible time-place transpositions, and the approximate date of cavern opening can be determined for each site. In each case this date represents a *terminus post quem* for the accumulation of hominid-bearing deposits.

ABSOLUTE dating of the early hominid cave deposits in South Africa has long been of concern to anthropologists, because unresolved problems of taxonomy and phylogeny stem largely from a lack of comparative chronological data for these sites. In particular, the chronological position of *Australopithecus africanus* remains in doubt. Faunal assemblages from the South African sites are often too restricted in their range of species to permit correlations either between sites, or with dated assemblages from East Africa.

Although radioisotopic and other techniques have been applied to the South African sites no absolute dates have been obtained. I therefore set out to investigate the possibility of applying geomorphological techniques of age determination in the hope that these might throw light on the date of accumulation of the South African cavern deposits.

Erosion Cycles

The method is based on a quantitative assessment of rates of cyclic erosion relative to well-established geomorphological datum levels. Since the Jurassic the African continent has been subject to five active episodes of epeirogenic movement, separated by intermissions in which erosion has advanced inland from the coast, with concomitant sedimentation of the continental shelf. The ages of these movements and the resulting offshore deposition are well known on the basis of both tectonic and marine palaeontological studies¹⁻⁵.

The recurrent pattern of continental landform development which succeeded each active episode has been the subject of detailed analysis^{6,7}; it is significant that recession of valley nickpoints inland from the coastal margin was

followed by valley widening, scarp retreat and pedimentation, leading ultimately to the formation of gently undulating pediplains or erosion surfaces. Where such surfaces have reached an advanced stage of planation local relief is minimal, and their distribution may be mapped very accurately. In some areas such as the South African Highveld, these plains extend unbroken for thousands of square km, and transgress both structure and lithology without interruption. Their existence in the African landscape is irrefutable, and their distribution has been described and mapped by several workers^{2-4,7-12}.

The erosion cycles seen near the South African hominid deposits are the African and Post African I. The most recent (Plio-Pleistocene) cycle is represented over much of South Africa by gorges incised into the coastal hinterland, and advanced planation referable to it is restricted to local basins. The date of inception of these cycles, based on palaeontological studies of the equivalent marine sediments, is as follows:

Table 1 Erosion Cycles in South Africa*

Cycle	Marine depositional equivalent	Date of inception
African	Littoral Senonian strata of east coast, with succeeding Eocene in Mocambique; Late Cretaceous and Eocene strata of Angola	Mid-Cretaceous (100 m.y. BP)
Post African I	Burdigalian marine series	Miocene (20 m.y. BP)
Plio-Pleistocene	Red "Berea" and other coastal sands	(2 m.y. BP)

* Adapted from King³.

The African erosion surface is characteristically well planed and provides a readily identifiable datum level in all areas unconsumed by later incision; however, local deformations along well defined axes are present, and are related to the tectonic disturbances which initiated the Plio-Pleistocene incision¹³. One such axis coincides with the Continental divide along the Witwatersrand ridge some 30 km to the south of the Sterkfontein and Swartkrans sites, and has resulted in upwarping of the African surface evident in the marked northerly tilt of discontinuous benches eroded in this cycle along the upper flanks of the Bloubaan Valley. Here African benches decline in elevation downstream at approximately 6 m km⁻¹.

Fig. 1 Map of South Africa showing hominid sites, drainage systems and nickpoints referred to in text. ●, Hominid sites; PP |, Plio-Pleistocene nickpoint; PA ||, Post-African nickpoint.

Nickpoint Migration

Figure 1 shows the locations of the sites and drainage systems which I discuss. The positions of the African, Post-African I and Plio-Pleistocene nickpoints, which represent the furthest point reached by incision in each cycle, are indicated relative to the streams concerned. In every case the hominid site is situated in a valley incised below the African erosion surface in the Post-African erosion cycle; valley or cave opening therefore occurred under the influence of this incision.

Figure 2 provides a graphical representation of the rate of nickpoint migration inland from the coast expressed as a proportion of the total stream length. The rate of nickpoint migration has been calculated by measuring the length of the stream channel segments affected by the Plio-Pleistocene and Post-African I incision. The mean rate of nickpoint migration was then plotted in relation to that proportion of the channel length represented by the mid-point of each segment, taking into account the position of the coast at the time of inception of the cycle which produced the nickpoint concerned. In the absence of supplementary evidence, it was assumed that the nickpoint migration rate between each of these points was subject to a linear decline culminating in zero at the point of origin of the stream in the watershed area.

This assumption is, of course, erroneous in that nickpoint migration rates are undoubtedly influenced by variations in lithology, climate, tributary flow and sediment load. Most of these influences are not, however, susceptible to quantitative assessment, although reference to Table 2 shows that the lithological composition of the valleys is comparable in each basin. Hence lithological modifications of the linear relationship are likely to be generally equivalent in each case. Moreover the errors in the use of the linear interpolation technique are likely to be reduced greatly by the close proximity of each site to the headwater of the local stream (see Fig. 1). In no instance does this exceed 14.24 km or 2.71% of the channel length, and migration rates so near to the stream source are so low, owing to the small available erosive potential, as to be little affected by possible departures from the linear mode of decline.

The nickpoint migration graphs presented in Fig. 1 demand some comment. Reference should be made to Table 3 in which the measurements from which the graphs have been constructed are presented. The graphs are numbered 1, 2 and 3 to indicate the drainage systems concerned: (1) the Limpopo-Magalakwin-Makapan drainage system, containing the Makapansgat limeworks site (*a*); (2) the Limpopo-Crocodile-Bloubank drainage system, containing the Sterkfontein and Swartkrans sites (*b*); (3) the Orange-Vaal-Harts-Buxton drainage system, containing Taung site (*c*) at the Buxton lime quarry.

Table 2 Occurrence of Various Lithological Types in Drainage Basins

Rock types	% of total channel length in drainage basins		
	1*	2*	3*
Moderately resistant Palaeozoic and Mesozoic sediments	30.25	29.43	27.06
Resistant Precambrian basic igneous rocks, largely plutonic	2.52	3.65	1.65
Resistant Precambrian acid igneous rocks and gneisses, largely plutonic	38.23	44.00	36.93
Very resistant Precambrian sediments and meta-sediments	29.00	22.92	34.36

* Drainage basins: 1, Limpopo-Magalakwin-Makapan; 2, Limpopo-Crocodile-Bloubank; 3, Orange-Vaal-Harts-Buxton.

The lower reaches of drainage systems (*a*) and (*b*), below the Magalakwin-Limpopo confluence, are common in the lower course of the Limpopo river, which enters the Mocambique coastal plain just to the east of the South African border. This plain is largely underlain by marine sediments, and was elevated to its present position by post-Miocene movements⁶. For this reason the segment of the Limpopo channel crossing it was ignored in measuring the extent of Post-African I nickpoint recession from the coast.

All three graphs are of similar form with a conspicuous inflection indicating substantially different rates of nickpoint

Fig. 2 Rate of nickpoint migration inland from coast. Sites, *a*, Makapansgat limeworks; *b*, Sterkfontein and Swartkrans; and *c*, Taung. Drainage systems: (1) Limpopo-Magalakwin-Makapan; (2) Limpopo-Crocodile-Bloubank; and (3) Orange-Vaal-Harts-Buxton.

migration in the Post-African I and Plio-Pleistocene erosion cycles. The more rapid rate of recession in the Plio-Pleistocene cycle is undoubtedly the result of the greater magnitude of the associated uplift and warping of the continental margin. Variations in rates of nickpoint migration between the different drainage systems may be explained by differences in the degree of stream activity, as dictated by volume and regularity of flow. Hence the lowest rates are evident in the Limpopo-Magalakwin-Makapan system which is non-perennial over much of its length, and the highest rates occur in the Orange-Vaal-Harts-Buxton system, which is subject to a more regular flow, particularly below the Vaal-Harts confluence.

From these measurements it is possible, to determine the mean rate of nickpoint migration between each site and the current position of the Post-African I nickpoint, which is situated in each case a short distance upstream. In all drainage basins this channel segment is contained almost entirely within the lower part of the Dolomite Series, Transvaal System, so that the calculated migration rates should not involve errors caused by major lithological variations. Division of this distance by the mean rate of nickpoint migration associated with it, gives the date before present of the arrival of the Post-African I nickpoint opposite each site. These dates are given in Table 3. They merely provide, however, a *terminus post quem* for the valley deepening and widening during which cavern opening occurred, or the locale was created for the accumulation of the hominid-bearing deposit. In order to determine the further time lapse required for this to occur it is necessary to consider briefly the geomorphological environment of each of the sites.

Analysis of Cave Sites

All of the deposits occur at similar stratigraphic levels within the Dolomite Series, which consists of interbedded

horizons of soluble dolomite and insoluble chert. This rock is subject to cycles of solution and cavern development closely linked to the cycles of subaerial erosion described previously^{10,11}. After the solutional formation of a cavity beneath the water table, incision and reduction of local base level produced lowering of the phreatic surface; concomitant valley widening caused the land surface to intersect the cavity creating an opening to the surface, commonly through a vertically enlarged joint or aven. This opening permitted the ingress of externally derived hillside soil, as well as hominids and animals. Hence, to determine the date of the earliest accumulation of the cave deposit, it is necessary to determine the time period which elapsed between arrival of the new erosion cycle opposite the site and recession of the valley side to a point at which cavern opening occurred.

The situation described above pertains in the case of the Makapansgat Limeworks, Sterkfontein and Swartkrans deposits, but the Taung deposit accumulated in cavities developed in a series of calcareous tufas deposited on the valley flank at Buxton subsequent to the incision of the valley in the Post-African I erosion cycle¹⁴. Hence the geomorphological controls governing cavern opening do not apply in this case, and all that may be deduced is that the hominid-bearing deposit post-dated the arrival of the Post-African I nickpoint (0.87 m.y. BP).

In the case of the dolomite cavern deposits, the time lapse involved in the widening of the valley to produce cavern opening has been calculated as a proportion of the total valley widening in the Post-African I cycle that has occurred to date. Figures 3 and 4 show topographic sections through the Makapan and Bloubank valleys at the limeworks, Sterkfontein and Swartkrans site, together with the local elevations of the African erosion surface. These elevations were determined through the construction and superimposition of numerous transverse and longitudinal profiles over large areas in the vicinity of each site. Both valleys are composite, in that they have been incised in both the

Table 3 Nickpoint Recession

Drainage system	Total trunk channel length (km)	Headward recession of cyclic nickpoints Distance from coast (km)	% of total channel length	Rate of recession (km per m.y.)	Distance of site from coast as % of channel length	Distance of oldest upstream nickpoint from coast as % of channel length	Mean rate of recession between site and oldest upstream nickpoint (km per m.y.)	Distance between site and oldest upstream nickpoint (km)	Date in m.y. BP of arrival of oldest nickpoint opposite site	Proportion of total valley down-cutting and widening (%) in locally current erosion cycle required to open cave	Date in m.y. BP of cave opening
Limpopo-Magalakwin-Makapan	570.15	Plio-Pleistocene: 497.80 Post African I: 566.21	87.30 99.28	248.90 28.36	Makapansgat limeworks: 98.78	99.28	0.55	2.86	5.24	30.00	3.67

Fig. 3 Section through Makapan Valley at limeworks (see text for explanation).

African and Post-African I erosion cycles, but the presence of benches, whose projected elevations accord with one another and with nearby areas of African planation, leave no doubt as to the portion of the incision referable to the Post-African I cycle.

To determine the approximate time required for valley widening to open the caverns, a line was drawn between the base of the present stream channel and the point of intersection of the African surface with the present valley side (line CD). A parallel line was drawn through the projected apex of the aven through which cavern opening occurred, and another was inserted to indicate the downward path of the stream channel during its incision from the African level to its present position (line ABC). It should be noted that these latter lines are not vertical, but assume varying inclinations in the three sections. This reflects lateral channel migration during the course of incision, partly in conformity with the local dip of the dolomite strata, partly as a result of asymmetrical downcutting in relation to the slip-off and undercut slopes of incising meanders. The original position of the channel at the level of the African surface was carefully determined in each case from distributions of benches and terraces occurring at this and subsequent levels.

The intercept AB is a measure of the amount of incision and valley widening required to open the cavern. This, expressed as a proportion of the total incision along the downward path of the channel (AC), represents that proportion of the time which elapsed subsequent to the arrival of the Post-African I nickpoint opposite the site, required to achieve cavern opening.

In this analysis of valley widening several assumptions have been made: first, that the valley flanks approximated to a rectilinear configuration during recession; second, that the downward path of the channel during incision was rectilinear; and third, that both channel incision and concomitant valley flank recession occurred at a regular rate. None of these assumptions is likely to be wholly accurate. The probable departures from these ideal conditions are, however, unlikely to have been sufficiently great to affect the relative dates or the general order of ages indicated in the

results, particularly because incision and valley widening occurred in very similar sedimentary successions at each site.

The proportions of valley flank recession required to open each cavern are presented in Table 3, and the resulting date for the first opening of each to permit the ingress of hillside materials, hominids and animals is given. These are approximately 3.7 m.y. for the Makapansgat limeworks, 3.3 m.y. for Sterkfontein, 2.6 m.y. for Swartkrans, and, as has been indicated previously, somewhat less than 0.87 m.y. for Taung.

Implications

These ages for the first opening of caverns or locales for the accumulation of hominid-bearing deposits embody certain errors inherent in the assumptions made during their derivation. It is, however, considered unlikely that they are large enough to affect the relative dates or general order of ages that have been deduced for two reasons: first, the lithological compositions of the channels are generally similar in each basin, and almost identical between each site and its upstream nickpoint; hence possible error factors caused by lack of lithological homogeneity are likely to be fairly evenly spread relative to the various sites. Second, interpolations for valley downcutting and widening at each site have been carried out relative to the actual profile of the valley section; hence local erosional irregularities have been considered.

Fig. 4 Sections through Bloubank Valley at Sterkfontein and Swartkrans (see text for explanation).

Comparisons of faunal material from all sites, and the remains of *Australopithecus robustus* from Swartkrans, with similar dated material from East Africa, have suggested that the deposits at Makapansgat limeworks, Sterkfontein and Swartkrans may be at least 0.5 m.y. younger than is indicated by the dates presented here^{15,16}. It should, however, be borne in mind that these dates are for the earliest cave opening, and that strata may be present in the lower levels of the deposits which are older than those from which the comparative material was derived. Such early strata of substantial thickness have recently been recorded both at Makapansgat and Sterkfontein. Furthermore, as Butzer¹⁷ has pointed out, the local production of hillside soil which forms the bulk of the breccias is extremely slow, and tens or even hundreds of thousands of years may have been required for such extensive deposits to accumulate. The young date for the Taung site is somewhat surprising, although Wells¹⁸ has suggested, on faunal grounds, that the accumulation of the Taung hominid deposit may have occurred later than was previously thought.

I hope that, in the absence of suitable isotopic dating methods, these results may provide less precise interim data until other chronometric techniques are developed.

I thank Professor P. V. Tobias for comment and encour-

agement. This article was adapted from the Chairman's address to Witwatersrand Centre, South African Archaeological Society, delivered February 28, 1973.

Implications of the New Age Estimates of the Early South African Hominids

PHILIP V. TOBIAS

Department of Anatomy, University of the Witwatersrand Medical School, Hospital Street, Johannesburg

Divergences exist between recent faunal and geomorphological estimates of the age of several South African australopithecine sites. New stratigraphic evidence from Sterkfontein and Makapansgat suggests a lengthy lapse of time between cave opening and deposition of dated fossil bones, and thus provides a basis for explaining the apparent discrepancies. The young date inferred for the Taung skull makes it up to 2 m.y. more recent than *Australopithecus africanus* from the Transvaal caves. As Taung is clearly not a member of *Homo erectus*, it is reasonable to hypothesise that it may be a later survivor of *A. robustus*.

UNTIL very recently, a lack of 'absolute' or of radiometric dates for the South African early hominids has vitiated any attempt to achieve a reliable synthesis between the South and East African early hominid lineages. Faunal comparisons, often based on rather inadequate fossil assemblages, had indicated two broad groups of fauna—an earlier group, known formerly as the Sterkfontein Stage^{1,2} and subsequently as the Sterkfontein Faunal Span³, and a later group, the Swartkrans Stage, renamed the Swartkrans Faunal Span. The term faunal span was introduced to connote both a particular faunal assemblage and the temporal duration of its existence. The faunas from Sterkfontein, Makapansgat and Taung had been provisionally assigned to the earlier span and those of Swartkrans and Kromdraai to the later span^{4,5}.

Up to the middle nineteen-sixties, these intraregional faunal comparisons had led to the view that the South African sites could be arranged, from oldest to youngest, as

follows: Taung→Sterkfontein→Makapansgat→('Sterkfontein Extension Site')→Swartkrans→Kromdraai.

Wells has, however, doubted for some time^{5,6} whether the faunal evidence justifies the view that Taung with its type specimen of *Australopithecus africanus* is indeed the earliest South African australopithecine site. The hominid-associated fauna could just as readily be equated with that of Swartkrans or even of Kromdraai: and most of the identified faunal elements belong to parts of the Taung deposit which is appreciably older than the *Australopithecus breccia*. The latest check-list of cercopithecoids⁷ shows the significant absence from Taung of *Parapapio broomi*—which is the commonest cercopithecoid at Makapansgat and Sterkfontein. Moreover, there are two species of *Papio* at Taung, another two at Kromdraai and one at Swartkrans, but none at Makapansgat or Sterkfontein. It would certainly seem that the primates in the Taung cercopithecoid breccia are younger than those of the Sterkfontein Faunal Span. The analyses of Peabody⁸ and Butzer⁹, in turn, agree that the cercopithecoid breccia is appreciably older than the *Australopithecus breccia* at Taung: Butzer places them in two successive phases of one geomorphological cycle, namely Norlim 2 and 3. So the Taung hominid is younger, by a still greater margin, than the Sterkfontein Faunal Span.

Until 1970, the seriation of South African early hominid sites was based on such purely relative faunal dates. Meantime, faunal successions in East Africa were being calibrated with some precision by suites of potassium-argon dates. The next logical step was to attempt indirect dating of the South African sites by correlation of their faunas with the well-calibrated lineages of East African fauna. This was first attempted by Cooke¹⁰, who provisionally suggested that the Sterkfontein and Makapansgat breccias may be about twice as old as has hitherto been thought, possibly "in the vicinity of 2.5 to 3.0 million years old". This was based on a comparison of the fossil suids from both South African sites and of *Elephas recki* from Makapansgat (*contra*¹¹) with their well-dated counterparts from East Rudolf and Omo (Shungura Formation). Cooke's view is supported by Maglio¹², who feels that although the faunal evidence is far from adequate and further studies are needed, both Maka-

pansgat and Sterkfontein seem to correlate best with the East African faunal succession of about the middle Shungura and lowest Koobi Fora formations^{13,14}. In terms of absolute chronology, Maglio believes that 2.5 m.y. is a fair estimate of the age of these faunas. Similarly, Cooke¹⁰ has suggested, on faunal comparisons, that Swartkrans is at least as old as Bed I, Olduvai (~1.8 m.y. for the Upper Member of Bed I). These tentative faunal datings have suggested that the deposits of Makapansgat and Sterkfontein are much older than had been supposed, whereas that of Taung seems to be far younger.

The new geomorphological studies, carried out by Partridge and announced in this issue of *Nature*¹⁵, as well as those of Butzer⁹, have provided the first guarded corroboration of the faunal dates provisionally claimed by Cooke and Maglio. In spite of their use of very different approaches, both Partridge and Butzer have arrived at a relatively young age for the Taung deposit. Moreover, Partridge has provided the first evidence suggesting approximate dates for the opening of the Makapansgat (3.7 m.y.), Sterkfontein (3.3 m.y.) and Swartkrans (2.6 m.y.) caves.

These admittedly conjectural estimates suggest that the Makapansgat cave opened earliest; that of Sterkfontein about 400,000 yr later, and that of Swartkrans, some 700,000 yr thereafter. It has not yet been possible to date the Kromdraai fissure deposits by these methods; Taung would be not older than Swartkrans and Kromdraai on Butzer's analysis, and as young as <0.87 m.y. by Partridge's approach: that is, about 1.0 m.y. younger than Swartkrans.

Partridge's method of dating is still, of course, exploratory and in its application to this problem as yet unconfirmed. Even if the method is still subject to refinement, it may be of value here to examine the degree to which his provisional dates fit other known facts and interpretations. Such a preliminary assay may, indeed, assist in putting Partridge's method to the test.

Makapansgat and Sterkfontein

Non-calibrated faunal comparisons among the South African sites had already led Wells⁶ to infer that some of the many points of difference between the faunas of Makapansgat and Sterkfontein might plausibly suggest that Makapansgat is the older of the two. This inference would now seem to gain support from Partridge's estimates for the opening of the caves, namely 3.7 and 3.3 m.y. respectively.

As has been shown, comparisons with the calibrated fauna of East Africa point to 2.5 m.y. or 2.5–3.0 m.y. for Makapansgat and Sterkfontein. There is thus a discrepancy between geomorphological and faunal estimates of 1.2–0.7 m.y. for Makapansgat and of 0.8–0.3 m.y. for Sterkfontein. It may pertinently be enquired if these are real discrepancies or technical ones. On the one hand, the divergences may be the consequence either of a methodological difficulty or lack of refinement in the geomorphological approach used, or of a problematical correlation, or of an error of faunal sampling. On the other hand, the departure between the two estimates may reflect a long lapse of time between the earliest opening of the caves and the deposition of the fossils which have been correlated with East African lineages.

Recent work at Sterkfontein¹⁶ has demonstrated the existence of an earliest bone-bearing breccia under the thick travertine once regarded as the floor of the main deposit (ref. 17, and unpublished work of T. Partridge, A. B. A. Brink and A. R. Hughes). This breccia may extend downwards for a considerable depth into the underground cave system (personal communication from J. Wilkinson). The accumulation of this lowest breccia followed the opening of the cave, but preceded the deposition of the stratigraphically much higher fauna on which the faunal dating has been based. In other words, the early stages in the

accumulation of the Sterkfontein deposit may have lasted far longer than had been imagined. This new stratigraphic evidence accords well with the lapse of a lengthy interval between the first opening of the cave (estimated at 3.3 m.y.) and the accumulation much higher in the deposit of the fossil bones on which the provisional faunal dating (2.5–3.0 m.y.) is based. Already, Butzer¹⁸ has inferred that "the Transvaal cave fills record, at the very least, several tens of thousands of years . . . and, quite possibly, several hundreds of thousands of years". In the light of this stratigraphic evidence, Partridge's estimate of a date of the order of 3.3 m.y. for the first opening of the cave is not wholly unexpected; nor is it incompatible with the provisional faunal date based on suids.

At Makapansgat, it was until recently uncertain whether there was comparable stratigraphic evidence to support a lengthy interval between the date estimated for the opening of the cave (3.7 m.y.) and the deposition of suid and elephant bones on which the tentative faunal dating (2.5–3.0 m.y.) has been based. During excavations at Makapansgat Limeworks in July 1973, I located a considerably older, lower breccia. In the Lower Cave, a conspicuous sheet of travertine has for long been regarded as lying on the original floor of the cave. Above this travertine is an accumulation of red, water-laid breccias, overtopped by the bone-rich grey breccia (which has yielded most of the hominids and datable fauna), which in turn is succeeded by the cercopithecoid-rich pink breccia, on which lies a surviving scale of the dolomite roof. The fauna used for comparison with the East African suids and proboscideans derives from layers well above the travertine floor. During our most recent excavations, in the lowest-lying parts of the cave, I located a succession of breccias and travertines below the supposed basal travertine; some of these oldest breccias proved to be bone-bearing.

Thus, at Makapansgat, as at Sterkfontein, there is stratigraphic evidence suggesting a lengthy lapse of time between the earliest opening of the cave and the deposition of those bones used for comparison with East African faunas. This evidence would suggest a much older date for cave opening than for the calibrated fauna. Against this background, Partridge's suggestion that the date of cave opening was of the order of 3.7 m.y. is not wholly unlikely; nor does it seriously contradict the faunal date of 2.5–3.0 m.y. tentatively inferred by Cooke and Maglio.

Both at Makapansgat and at Sterkfontein, it now seems not altogether improbable that the filling of the caves may have occupied between 0.3 and 1.2 m.y. The upper part of this range of time is sufficiently long to make it likely that significant changes of fauna and perhaps of culture may be entombed within the deposit. Already there is some evidence to suggest a succession, at both Sterkfontein and Makapansgat.

The earlier age inferred for the Makapansgat deposit seems to be in keeping with the evidence of the hominids themselves. The Makapansgat hominids are characterised by 'gracile' or *A. africanus* features, but include as well some *A. robustus* traits in crania, jaws and teeth, to which attention was drawn in 1967: "In these respects, the Makapansgat specimens seem to show a somewhat nearer approach to *A. robustus* than do the Sterkfontein specimens"¹⁹. This led me subsequently to suggest tentatively that more than one species of hominid is present at Makapansgat^{20,21}. From a study of the mandibles, Aguirre²² has since claimed that the Makapansgat juvenile jaw, MLD 2, indubitably represents a young male *A. robustus*.

In the light of the new tentative age determinations for Makapansgat, it might be suggested that a *mélange* of *A. africanus* and *A. robustus* features might have been expected in an early population of *A. africanus*, close to the point of speciation into robust and gracile species. As an early population, it is reasonable, in Darwinian and in genetic

terms, to suppose that its spectrum of anatomical polymorphisms adumbrates later speciation of the *A. robustus*-*A. boisei* lineage from a basic *A. africanus* lineage.

Swartkrans

The Swartkrans Faunal Span is younger than the Sterkfontein Faunal Span. The Swartkrans fauna itself is considered older than that of Kromdraai and than the Cornelia Faunal Span (from Cornelia, Orange Free State)⁶. Partridge's new study has tentatively inferred a date of 2.6 m.y. for the opening of the Swartkrans cave, and Cooke, on the fauna, has estimated an age of roughly 1.8 m.y. at least. Again there is an apparent discrepancy, this time of about 0.8 m.y., between the two estimates: but both confirm what intraregional faunal comparisons have indicated, that Swartkrans is younger than Makapansgat and Sterkfontein. Brain's excavations at Swartkrans^{23,24} may yet reveal whether there is a stratigraphic explanation for the gap between the two claimed dates at this site.

Taung

The type-site of *Australopithecus africanus*, Taung, was long regarded as the oldest of the South African early hominid sites. Wells pointed out that the species most closely associated with the juvenile hominid skull do not warrant this view, and that Taung could equate with Swartkrans or even Kromdraai^{15,6}.

Butzer and Partridge agree that Taung is much younger than Makapansgat and Sterkfontein, claiming that it is either coeval with or younger than Swartkrans-Kromdraai (Butzer), or younger than 0.9 m.y. BP (Partridge). The second estimate refers to the *terminus post quem* for the formation of the original Taung cavern: on this conjecture, it would follow that the lower, cercopithecoid breccia is somewhat younger than <0.9 m.y., and the upper, *Australopithecus* breccia would be still younger, perhaps 0.8 or even 0.7 m.y. BP. If, as Cooke suggests¹⁰, the age of the Swartkrans fauna is at least 1.8 m.y., Butzer's maximum age for Taung would be 1 m.y. earlier than Partridge's tentative estimate. On the other hand, Butzer agrees that Taung may be younger than Swartkrans—and this would reduce the discrepancy between his and Partridge's estimates. It is not possible at present to determine if any residual discrepancy would have a real, stratigraphic basis, or be only apparent, the result of errors in either or both estimates.

In any event, one can only conclude that, far from being the oldest australopithecine site in southern Africa, Taung is probably the youngest. What is more, it may compete with Chesowanja and Peninj (both just over 1.0 m.y. BP) as being the site of the most recent survival of an australopithecine anywhere in Africa. In Fig. 1, Taung has been plotted at about 0.8 m.y., with an interrupted line extending back to the approximate date of Kromdraai.

On the basis of Partridge's estimate, the Taung skull, the type specimen of *A. africanus*, represented a hominid that lived up to 2 m.y. later than the Makapansgat and Sterkfontein hominids, which are generally regarded as belonging to *A. africanus*. Between the two periods of 2.5–3.0 m.y. and 0.8 m.y., no trace of *A. africanus* has been identified in southern Africa, even though two sites (Swartkrans and Kromdraai) are probably dated to the intervening period. In East Africa, hominids datable to the intervening period have been attributed, in the main, to the robust australopithecines (the superspecies, *A. robustus*/*A. boisei*²⁵) and to *Homo* sp. Furthermore, some workers have claimed to recognise the presence of *A. cf. africanus* at Omo (chiefly isolated teeth) and at Olduvai (for example, Olduvai hominid 7, recognized by Leakey *et al.*²⁶ as the type specimen of the bigger-brained *H. habilis* and regarded by others as *A. habilis*). Thus, the presence of *A. africanus* in East Africa between 2.5–3.0 m.y. and 0.8 m.y. remains disputed and

Fig. 1 Provisional temporal distribution of East African hominids (after Maglio¹²) and of South African hominids (based on the new dates).

equivocal. The most convincing East African claimant for membership of *A. africanus* is the far older Lothagam mandible²⁷ dated to about 5.0–5.5 m.y.²⁸.

Phylogenetic Implications

Figure 1 depicts the dates of the South African sites, based on the latest provisional faunal datings and modified somewhat by the geomorphological estimates of Partridge. These are compared with those for East Africa as formulated by Maglio¹².

In Fig. 2, an attempt has been made to represent the various hominid taxa living at 0.5 m.y. intervals in South and East Africa. Although there are several different classifications of hominids, I have used a bigeneric one, because the recognition of two Plio-Pleistocene hominid genera, *Australopithecus* and *Homo*, enjoys the greatest consensus at the present time^{25,29}. Furthermore, I have used a division of *Australopithecus* into *A. africanus*, *A. robustus* and *A. boisei*, the last two being considered as two allopatric species forming one superspecies²⁵; and of *Homo* into *H. habilis*, *H. erectus* and *H. sapiens*.

In Fig. 3 I have made a new reconstruction of the phylogeny of the Plio-Pleistocene hominids, using the new tentative South African hominid age estimates. The early origin of *Homo* in the figure is based on the probable date of 2.9 m.y. for R. E. F. Leakey's new cranium, KNM-ER 1470, found below the KBS tuff of East Rudolf³⁰. From my examination of this important find, kindly permitted by Mr Leakey, I am impressed by the morphological resemblances between ER 1470 and the crania assigned to *H. habilis*. Tentatively, I accept Leakey's attribution of ER 1470 to *Homo* sp.: as a provisional judgment, it may even extend our concept of the range, in time and morphology, of *H. habilis*.

If the late date proposed for the Taung child is more or less correct, its only known contemporaries are *Homo* (most

probably *H. erectus*) and the last-surviving members of the robust australopithecine superspecies (Fig. 2). The inferred date of about 0.8 m.y. BP makes it >1.0 m.y., and probably about 2.0 m.y., more recent than the latest of the other African fossils assigned to *A. africanus*.

Hence, it may well be questioned whether the Taung child does in fact represent *A. africanus*, in the sense in which this taxon is defined from Makapansgat and Sterkfontein. The possibility of isolated relict populations of *A. africanus* having survived in the southerly cul-de-sac of Africa for 1 to 2 m.y. after the species had disappeared elsewhere, or had given rise to the earliest species of *Homo* in Africa, cannot of course be excluded. On the other hand, because its small brain³¹ and its dental characters would exclude it from *H. erectus*, it must seriously be considered whether the Taung child is not a late surviving member of *A. robustus* or *A. cf. robustus*. Although nearly 50 yr have elapsed since its discovery³², it is true to say that the Taung skull has never yet been fully analysed and described. In my laboratory, G. R. Sperber has recently made X rays of the Taung maxilla and mandible which reveal the unerupted permanent premolars and second molars. A careful radiological study of these tooth germs, and the possible extraction of two of them, may provide additional and perhaps diagnostic dental evidence on the affinities of the Taung child. Certainly, the recent discovery of new juvenile specimens of *A. robustus*²⁴ and other early hominids would make a definitive study of the Taung skull both timely and potentially most rewarding. It is hoped that such a study would provide evidence to confirm—or refute—the hypothesis that the Taung child represents a member of *A. robustus*.

Fig. 2 Hominid populations in Africa at various times in the Plio-Pleistocene. The oval figures at each time level represent the various systematically identified, synchronic hominid taxa living in Africa. The horizontal distance between a pair of ovals at the same time level is roughly proportional to the morphological and taxonomic distance between the populations or taxa represented by the ovals.

Fig. 3 Provisional phylogenetic tree of the Plio-Pleistocene Hominidae. The possible extension of *A. africanus* and/or *A. robustus* to a very recent period (<1.0 m.y. BP) is suggested as two alternative means of accommodating the Taung skull at its new young date (0.7–0.8 m.y. BP).

Taxonomic Implications

If the Taung skull has to be removed from the paradigm of *A. africanus* and included in that of *A. robustus*, the specimen's place as the holotype of *A. africanus* would have to be revised. In any event, since the nominal species, *A. africanus*, was based on an immature stage lacking, to a certain extent, good diagnostic characters, the designation of a lectotype under Article 74 of the International Code of Zoological Nomenclature would seem desirable. The inclusion of the Taung skull in *A. robustus* would not automatically lead to its designation as the type specimen of this species: its juvenile status would probably preclude it from being so designated and the holotype of *A. robustus* would remain the skull, teeth and postcranial bones of the adult specimen, TM 1517, from Kromdraai, Transvaal.

I thank Dr V. J. Maglio for allowing me to quote from his unpublished manuscript, and also Dr T. C. Partridge, Professor K. W. Butzer, Mrs Kay Copley, Mr P. Faugust, Mr A. R. Hughes, Miss C. J. Orkin and Miss J. Walker. Ionospheric Effects of Cosmic γ -ray Bursts

THE recent discovery of bursts of γ rays of cosmic origin¹ has led to the suggestion that these bursts might produce observable ionospheric effects. Since γ rays are absorbed at a relatively low altitude when compared with most other types of ionising radiation, the thought was that these bursts would produce additional ionisation which might be strong enough to affect v.l.f. radio propagation data. If so and if data from several paths were obtained, it might be possible to obtain information about the location of the sources. Directional information from the Vela satellites, when obtained at all, contains an inherent ambiguity.

The calculations reported here were carried out by means of a Monte Carlo code which was developed to calculate X-ray and γ -ray transport in a model atmosphere. The model used is based on the 1962 COESA standard atmosphere². In the code it is described by 120 plane parallel layers, with each layer 1 km thick. Within each layer the density is assumed to decrease exponentially with altitude, and is described by a tabulated initial density and scale height for each zone. Above 120 km the atmosphere is assumed to provide negligible photon attenuation. The atmosphere is considered to have constant chemical composition, with photon cross sections as given by Storm and Israel³. Up to 120 km this approximation is quite good, but begins to become invalid at higher altitudes. Electron transport is neglected; that is, a photon which is absorbed or loses energy in a Compton collision is assumed to deposit all this energy in the 1 km zone in which the interaction occurs. This is a valid approximation, since at altitudes of from 20 to 40 km, the region in which most of the interactions take place, the thickness of the individual layers ranges from 9 g cm⁻² to 0.4 g cm⁻². The range⁴ of the highest energy Compton electron which can be produced is approximately 0.35 g cm⁻²; the vast majority of the electrons have considerably lower energy.

A calculation of energy deposition requires a knowledge of the incident spectrum. Spectral information from the Vela satellites is only qualitative, being based on total counts in two overlapping channels, with energy responses covering the

ranges from 0.2 to 1 MeV and 0.3 to 1.5 MeV, respectively. But since the original announcement of the Vela discovery, it has been learned that several of these events were also observed by the Goddard Space Flight Center γ -ray detector on board IMP-6 (ref. 5), and that one was seen by the two USCD X-ray telescopes on board OSO-7 (ref. 6). The IMP-6 and OSO-7 instruments provide overlapping spectral information for one event, 72-4 in the Vela catalogue, covering the energy range from 11 to 800 keV. This spectrum was used in the calculations reported here.

Several simplifying assumptions about the nature of the source were made in carrying out the calculations. The spectrum was assumed to be independent of time, although for most of the events observed by the IMP-6 detector the spectrum seems to soften somewhat with time. The time history as observed by both the Vela and OSO-7 satellites shows complex structure, but in the calculations it was assumed that the burst rose above background instantaneously and decayed exponentially, with a time constant of 20 s.

Table 1 Atmospheric Energy Deposition by Cosmic γ -ray Burst 72-4, having Total Incident Energy per Unit Area of 3×10^{-4} erg cm⁻²

Zenith angle (degrees)	Peak energy deposition (eV cm ⁻³)	Altitude of peak energy deposition (km)
0	85	28
6	86	29
12	85	29
18	82	29
24	76	29
30	72	29
36	66	30
48	49	31
60	33	32
72	16	33
84	3	40

Peak total energy deposition for various zenith angles is shown in Table 1. The ionisation is not very strongly dependent on zenith angle over quite a wide range. This particular event is not the strongest that has been observed in terms of total energy incident on the atmosphere, but it is not untypical. The peak energy deposition of approximately 85 eV cm⁻³ corresponds roughly to an electron production of 2 or 3

electrons cm^{-3} . It occurs at an altitude considerably lower than what is usually considered the lowest part of the daytime D layer. At that altitude the only competing process is ionisation by galactic cosmic rays⁷. In fact, at high geomagnetic latitudes the magnitudes of the two effects are comparable. This is shown in Fig. 1, where the steady state electron density produced by galactic cosmic rays at geomagnetic latitude greater than 70° is compared with the total number of electrons produced over a period of 80 s by γ -ray burst 72-4.

Fig. 1 Total electron density produced by cosmic γ -ray burst 72-4 compared with the steady state electron density produced by galactic cosmic rays. Cross-hatched area covers extremes of night-time solar maximum and day-time solar minimum as calculated by Webber⁷ for geomagnetic latitude greater than 70° .

So the best chance of observing these bursts would be at low geomagnetic latitudes, where the ionisation induced by galactic cosmic rays would be of a lesser magnitude than that produced by the burst. The burst would produce only a very transient effect, since at the altitudes at which the peak ionisation occurs the effective recombination coefficient is a very rapidly increasing function of decreasing altitude⁷. This requires that data be recorded on a finer time scale than is usually the case when, for example, the effects of geomagnetic activity are being studied⁸.

This work was performed under the auspices of the US Atomic Energy Commission. I thank I. B. Strong for suggesting this study, W. H. Tucker and T. J. Rosenberg for suggestions and T. L. Cline and M. P. Ulmer for furnishing data in advance of publication.

Structure of the Terrestrial Planets

BULLEN¹ has suggested that to reconcile known data for Venus, Earth and Mars with the hypothesis that they have the same overall composition, the outer core of the Earth may be composed of Fe_2O . The principal reason seems to be the resolution of an alleged discrepancy between the modern solid radius of Venus determined by radar², $6,053.7 \pm 2.2$ km and the value of 6,270 km computed by Bullen on the phase-change hypothesis for the core³. But this latter value was arrived at on the basis of somewhat approximate calculations, whereas more accurate calculations⁴ find no discrepancy of any significance in interpreting Venus as possessed of three main zones with mechanical-elastic properties the same as in the corresponding zones of the Earth. In such calculations some allowance for the existence in Venus of a small inner core could readily be made, but it is clear that no adjustment for such an inner core, which in the Earth has volume only 0.76% of the whole, could seriously affect the computed value of the overall radius. For if the inner core were completely annihilated and the Earth contracted down geometrically without change of volume of the remainder, the outer radius would shrink only by 16 km, so that averaging of its properties with those of the main bulk of the core would produce negligible change of radius, whereas Bullen's discrepancy is over 200 km.

Although the possibility that the core consists of Fe_2O cannot be ruled out, there seems to be no need to postulate this, or any specific composition as to its chemical nature, when it comes to the question of calculation of the internal structures of other planets on the hypothesis that they have the same overall composition as the Earth itself; it is only the elastic constants and uncompressed density of the material that enter such calculations. Even if the properties of Fe_2O at pressures in excess of 10^{12} dyne cm^{-2} and temperatures of say 5,000 K ($\pm 2,000$ K) could be accurately calculated, its identification as core material could be based only on the agreement of its elastic constants and density with the known values derived for core material from the seismic data. Because these latter values are reliably known anyway for the Earth, they can be transferred immediately for use in regard to the other planets, without raising the question of absolute composition. When that is done the modern radar value for the solid radius of Venus leads to no difficulty in arriving at an acceptable internal structure. On the other hand, there could be no guarantee that other compounds may not have the same elastic properties and density as Fe_2O at the conditions concerned, and thus making detailed identification superfluous.

Adopting the round figure of 6,055 km for the radius, the model that is most plausible on the phase-change hypothesis has the following properties⁴: m_c =mass of core= 1.20×10^{27} g=0.247 mass of Venus; ρ_c =central density= 11.45 g cm^{-3} ; p_c =central pressure= 2.70×10^{12} dyne cm^{-2} ; r_c =radius of core=3,032 km=0.5008 radius of Venus; p_{12} =pressure at core/mantle boundary= 1.23×10^{12} dyne cm^{-2} ; r_m =radius to mantle/outer-shell boundary=5,540 km=0.915 R_V ; m_{12} =combined mass of core and mantle= 4.11×10^{27} g=0.844 M_V ; p_{23} =pressure at top of mantle= 0.16×10^{12} dyne cm^{-2} ; ρ_m =mean-density of whole planet to solid surface= 5.233 g cm^{-3} ; f =moment-of-inertia factor=0.3424; W =total (negative) gravitational energy= 0.1703×10^{40} erg.

If the pressure p_{12} at the core/mantle interface and the pressure p_{23} at the mantle/outer-shell interface were both assigned, then a unique surface radius r_s would result. Conversely, if the radius is regarded as known, then only one or other of these pressures is disposable. Where p_{23} is concerned, there is experimental evidence⁵ that the phase change involved is influenced by the temperature in the sense that higher pressure is needed to bring it about at higher temperature. In the Earth, the value of p_{23} is at present about 0.14×10^{12} dyne cm^{-2} . Calculations for Venus have been made³ covering a range of values of p_{23} from 0.12 to 0.16 ($\times 10^{12}$ dyne cm^{-2}),

and these show that the pressure p_{12} at the boundary of the core ranges only from about 1.22 to 1.27 ($\times 10^{12}$ dyne cm^{-2}), whereas the pressure at the core boundary in the Earth is 1.37 ($\times 10^{12}$ dyne cm^{-2}). If this boundary is regarded as an abrupt change of composition, then no special inference could be drawn from these lower pressures for Venus, but if it represents a phase change to metallic-liquid form, then this change being such that its production at lower pressure requires higher temperature, the inference would be that Venus is at somewhat higher internal temperature than is the Earth at this boundary. This is consistent with heating through radioactivity requiring longer for the central temperature to rise to an adequate level before bringing on the sudden Ramsey collapse^{6,7}, with part of the vast gravitational energy thereby released further increasing the temperature. For these reasons, a higher temperature might well also be implied for the mantle/outershell boundary, and the value 0.15 ($\times 10^{12}$ dyne cm^{-2}) was therefore selected to accord with this in settling the above most likely model. Venus would reach this stage later than the Earth, and its whole internal development may be lagging behind that of the Earth by some fraction of an aeon. Higher internal temperature for Venus might also receive some contribution through its greater proximity to the Sun coupled with a long-sustained greenhouse effect.

The proportion by mass of Venus in its core is seen to be 24.7%, compared with 31.4% for the Earth, and with the radius fixed at 6,055 km no serious change of this percentage is possible for any reasonable adjustment of the interface pressures. (If the radius is taken to be larger, the percentage is reduced.) Indeed, if Venus were to have the terrestrial properties by mass in its core, the radius could not be greater than about 5,980 km—more than 70 km less than the observed value. On the hypothesis that the terrestrial planets and the Moon have similar compositions, homogeneous on a sufficiently large scale, so that the known elastic constants and uncompressed densities for the various zones of the Earth can be utilized to compute models of these bodies, then the following scheme of possible explanation of their structures, as regards the presence or otherwise of a core, emerges from the presently known values of their masses and radii (Table 1).

Table 1 Properties of Terrestrial Planets

	Mass	Mean density	Percentage mass in core	Possible explanation
Earth	1.0	5.52	31.4	Iron or phase change
Venus	0.815	5.23	24.7	Iron or phase change
Mars	0.108	3.92	0.0	No metallic core
Mercury	0.055?	5.42?	60.0	Iron core only
Moon	0.012	3.35	0.0	No metallic core

For the purpose of computing the percentages of Table 1, no discrimination need be made between the time-honoured iron hypothesis and the Ramsey phase-change hypothesis for the terrestrial core, because the parameters needed depend solely on the seismic data for the Earth. On the first hypothesis, comparing the core masses with that of the Earth, each of the other bodies is seen from Table 1 to present a problem in varying degree. It would be necessary to suppose that Venus had distinctly smaller proportion of iron than the Earth, whereas the slightly more distant Mars and the closely adjacent Moon, without iron cores at all, would have considerably less proportion of iron overall and the present mass and radius of Mercury would require this planet to be a most remarkable object with about 60% of its mass in the form of an iron core and its whole iron content presumably greater still. On the phase-change hypothesis, however, these striking differences between the bodies follow immediately as a direct consequence of the internal pressures resulting from the differences in mass, the only difficulty being the egregious Mercury.

The value for the mean density of Mercury depends not only on that found for the mass but, even more sensitively, on that for the radius. Modern determinations, which are made by a combination of radar measures and dynamical theory, may nevertheless be influenced from the outset through the adoption, as starting values for linearized correction, of the mass originally announced by Rabe⁸ in 1950 from the orbit of Eros, and of the optically observed radius. Just as, to take a simple example, Newton's method may fail to find the appropriate root of an equation if the starting value selected happens to lie too close to another inapplicable root, so in the present case the situation may be such that arrival at the correct mass may automatically be prevented. This 1950 value for the mass has recently been practically withdrawn as to its reliability by Rabe⁹, who on further investigation of the method finds the (reciprocal) mass in fact to be subject to a probable error in excess of 50%. The difficulty of determining the radius of a small object lying so close to the Sun is of course so generally appreciated as to call for no further comment here.

The importance of the forthcoming Venus-Mercury flyby for resolving the seemingly anomalous structure of Mercury is self evident. Until confirmation by such means is available it seems scarcely worthwhile endeavouring to explain how it may have come about, or further still how the apparently strange composition may affect theories of the origin of the planets. On the basis of the phase-change hypothesis, a mean density for Mercury less than that of Mars would seem a reasonable expectation.

PROFESSOR BULLEN replies: The statement¹ that "The principal reason for [the Fe₂O proposal] seems to be the resolution of an alleged discrepancy between the modern solid radius [R_v , say] of Venus determined by radar . . . and the value computed by Bullen on the phase-change hypothesis" does not put the facts in correct perspective.

I gave² four independent objections to the phase-transition theory, the discrepancy over R_v being only one item. More potent objections³ are: (a) the difficulty of reconciling the phase-transition theory with the large density jump at the Earth's mantle core boundary; (b) the failure to obtain support for that theory from shockwave high-pressure experiments. These objections have caused perhaps a majority of geophysicists to "rule out" the theory. My estimate is that the above objections make it desirable to explore alternatives, of which the Fe₂O theory is one. That theory, in contrast to the phase-transition theory, has the special strength that it avoids the potent objections ((a) and (b)) while yielding fair agreement with the relevant observational data. Lyttleton¹ disregards this vital point.

I do not agree that my 1950 estimate³ of 6,270 km for R_v , which assumed the phase-transition theory, is less dependable than Lyttleton's later calculations^{4,5}. I regard the opposite as the case. My calculations used numerical integration along with direct numerical detail on the Earth's density and pressure

distributions, and the procedures were formally reliable within ~ 10 km for R_V . In contrast, Lyttleton's calculations introduced a number of implicit assumptions which I did not find necessary and which distorted the starting Earth model, making his numerical results distinctly less reliable than mine (see also ref. 6).

Further, Lyttleton shows a lack of grasp of what the Fe_2O theory does in respect of planetary core radii. He refers to the volume of the Earth's inner core being only 0.76% of the volume of the Earth and infers that the presence or absence of an inner core in Venus would therefore have negligible effect on the estimated R_V . What is not appreciated is that the very large reduction of order 200 km from my estimate of R_V on the phase-transition theory to that on my Fe_2O theory arose principally because the Fe_2O theory entails relatively larger inner cores in smaller planets; for Venus, the inner core is given as not merely relatively larger than in the Earth, but actually as having nearly six times the volume of the Earth's inner core. On the Fe_2O theory, the Venus inner core has 4.4% of the volume of Venus. A consequence is that the change in the estimated R_V on the two theories is by no means negligible.

Why then does the Venus model detailed in ref. 1 have a value so close to the present observed value of $\sim 6,050$ km. I attribute this partly to some of the unreliable features of Lyttleton's procedures (see ref. 6), partly to *ad hoc* assumptions made by Lyttleton, and partly to his provision for possible temperature differences; this provision places an additional parameter at his disposal in a way that amounts to a further *ad hoc* device.

A very important corollary to the substantially larger inner core for Venus entailed on the Fe_2O theory is that the outer core of Venus is small compared with the Earth's outer core. Thus (assuming the dynamo theory of planetary magnetic fields), the Fe_2O theory fits better than all other theories the failure to detect a magnetic field around Venus.

While conceding that my Fe_2O theory cannot be "ruled out", Lyttleton questions the need for postulating any specific composition in planetary interiors. I have already indicated that one important reason for proposing the Fe_2O theory is that it avoids the objections (a) and (b). Moreover, a key property of Fe_2O for present purposes is essentially physical—the instability assumed at pressures less than a critical pressure (which corresponds to that at the Earth's mantle-core boundary). It is conceivable that the Earth's outer core could be composed of another material which exhibits this instability; if such a material should be found there could be a case for its investigation in respect of planetary structure.

More serious, however, is the statement¹ that the "identification [of Fe_2O] as core-material could be based only on the agreement of its . . . density with the known values derived . . . from seismic data". No reference is made to Soroktin's calculations that Fe_2O has the assumed instability and that its density-pressure relation for conditions prevailing in the Earth's outer core matches that in recent Earth models (see, for example, ref. 8).

Lyttleton's comment on the considerable uncertainty of the observational mean density of Mercury is interesting. Because of the uncertainties it has seemed to me that all that can, on present evidence, be reasonably said on the internal structure of Mercury was said by 1952. It has long been established that "on the basis of the phase change hypothesis a mean density for Mercury less than that of Mars would appear to be a reasonable expectation" (see, for example, ref. 9).

No useful favourable test of Lyttleton's theory has emerged since it was promulgated some ten years ago, but there are² possible tests of the Fe_2O theory in the foreseeable future. I seem to differ from Lyttleton in that I do not wish to press any particular theory beyond what I regard as the balance of evidence. Should future tests favour the phase-transition theory, no one would be more delighted than myself because of my earlier association with it. But it seems to me that,

on a proper weighting of current evidence, including points (a) and (b) above, the Fe_2O theory has fewer difficulties to meet than the phase-transition theory.

Refining the Earth's Pear Shape

QUITE soon after the launching of the first artificial satellites, analysis of their orbits led to the reshaping of the world. The orbital plane of Sputnik 2 rotated less rapidly than expected, indicating¹ that the polar flattening was about 0.35% less (the polar diameter about 150 m greater) than had been thought. The variations in the perigee height of Vanguard 1, as perigee moved successfully north and south of the equator, showed² that the polar section of the geoid—the profile of the sealevel surface revealed by a cut through the poles—was not symmetrical about the equator but had a slight pear-shape tendency, with the stem at the North Pole. Floating at sealevel at the North Pole, one would be about 40 m further from the equator than an equally undaunted explorer who bored down to sealevel at the South Pole.

Since 1959 the odd zonal harmonics in the geopotential, which determine the extent of the pear shape, have been evaluated with improving accuracy and reliability, from analysis of satellite orbits at a wide variety of inclinations to the equator. But until recently no suitable satellites have been available with near-equatorial orbits or with orbits close to the critical inclination of 63.4° , where the perturbations caused by the odd harmonics become extremely large, 50 km or more. In this letter we report the results of a new determination of the odd zonal harmonics³ from the orbits of twenty-seven satellites, including two orbits close to the critical inclination, determined with the help of observations from the Hewitt cameras at Malvern and Edinburgh.

If variations with longitude are ignored, the geopotential U at an exterior point distant r from the Earth's centre and having geocentric latitude ϕ , may be expressed in the standard form¹

$$U = \mu/r \left\{ 1 - \sum_{n=2}^{\infty} J_n (R_e)^n P_n (\sin \phi) \right\} \quad (1)$$

where μ is the gravitational constant for the Earth ($398,601 \text{ km}^3 \text{ s}^{-2}$), R is the equatorial radius ($6,378.14 \text{ km}$) and $P_n (\sin \phi)$ is the Legendre polynomial of degree n and argument $\sin \phi$. The coefficients J_n are to be determined.

The variations of gravity with longitude, although ignored in equation (1), can be measured, and the variations of the geopotential with both latitude and longitude, in terms of tesseral harmonics, have been evaluated by analysing observations of satellites with cameras and lasers, and also by Doppler radio tracking, combined with ground-based data such as gravimetric measurements. Two recent examples are the Smithsonian Standard Earth III (ref. 4) and the Goddard Earth Model 4 (ref. 5). The neglect of the longitudinal variations in equation (1) means that U represents

a longitude-averaged potential, and therefore gives a longitude-averaged polar section of the geoid.

The even zonal harmonics, with coefficients $J_2, J_4, J_6 \dots$ are symmetrical about the equator; the odd zonal harmonics, with coefficients $J_3, J_5, J_7 \dots$ are antisymmetrical about the equator. The dots in the previous sentence nicely express the crux of the problem of determining the coefficients: how do you evaluate an infinite set of coefficients from finite data? In practice, the usual method is to analyse the orbital variations in as many satellites as possible, having the most varied available orbits, and to evaluate the coefficients by truncating the series of harmonics when the inclusion of further coefficients seems to bring no advantage.

Table 1 Values of Eight Coefficients

$10^9 J_3 = -2,531 \pm 7$	$10^9 J_{11} = 159 \pm 16$
$10^9 J_5 = -246 \pm 9$	$10^9 J_{13} = -131 \pm 22$
$10^9 J_7 = -326 \pm 11$	$10^9 J_{15} = -26 \pm 24$
$10^9 J_9 = -94 \pm 12$	$10^9 J_{17} = -258 \pm 19$

Our recent determination of the odd zonal harmonics⁸ utilised twenty-seven orbits, at inclinations to the equator ranging between 3° and polar, and we found the most satisfactory least-squares fit to the data was obtained by evaluating eight coefficients, J_3 to J_{17} . Their values are given in Table 1.

The values are determined by fitting the nearly sinusoidal variation in perigee height experienced by the twenty-seven satellites, and the effect of the complete set of harmonics is best characterised by the amplitude β of the oscillation in eccentricity which they produce in a standardised orbit. Figure 1 shows the values of β for an orbit with near-zero eccentricity and semi-major axis $a=7,087$ km ($=R/0.9$).

Fig. 1 Variation of β with inclination for $R/a=0.9$ and $e=0$, given by our solution (—), Wagner's⁶ (---) and Kozai's⁷ (-·-·-). Arrows indicate the inclinations of satellites in all three.

Fig. 2 Height of the meridional geoid section (—) relative to a spheroid of flattening 1/298.25 (---). (With our odd harmonics and Wagner's⁶ even harmonics.)

Figure 1 also indicates the amplitude of the oscillation in perigee height, $a\beta$, which is nearly independent of a . The diagram gives the value of β for our set of odd zonal harmonics (solid line); for that obtained from twenty-one orbits by Wagner⁶ (broken line); and for that obtained from fourteen orbits by Kozai⁷ (dot-dash line). Our predicted values of $a\beta$ agree with Wagner's to within 200 m except very close to 63.4°, but Kozai's values tend to oscillate about ours, and differ by up to 700 m at some inclinations. There are eight satellites common to all three of these determinations of the odd harmonics, and it is noticeable that the values of β agree well at the inclinations of these satellites, indicated by arrows in Fig. 1. Much of the difference between the three sets no doubt arises from the different individual coefficients evaluated: we chose J_3 to J_{17} ; Wagner chose J_3 to J_{21} ; and Kozai chose J_3 to J_{23} plus J_{35} .

Our previous set of odd zonal harmonics⁸ indicated that the pear-shape tendency of the Earth—the north polar radius minus the south polar radius—amounted to 40 m. The new set of values gives a geoid which is the same to within 1 m over most of the latitude range, but shows larger differences (of up to 2.3 m) at latitudes of 88° to 90°, with the north pole quite literally 'growing a stem', like a pear. Consequently the pear-shape tendency, as defined above, is now greater, 44.7 m instead of 40 m. In presenting a profile of the geoid, it is also necessary to choose a set of even zonal harmonics, and Fig. 2 shows the geoid profile (solid line) relative to a spheroid of flattening 1/298.25 (broken line) with our set of odd zonal harmonics and Wagner's set of even zonal harmonics⁶. (The use of Kozai's even harmonics⁷ does not alter the profile by more than 0.3 m.) Figure 2 shows that the north polar stem of the pear may be taken as 18.9 m high, whereas the south polar depression is 25.8 m below the spheroid. Since the change from the 1969 values amounted to less than 1 m over most of the latitude range, the profile in Fig. 2 should be accurate to 1 m, although of course it represents an average over all longitudes rather than a specific physical profile.

In conclusion we emphasise that, in spite of the good accuracy of the geoid section, there is still much room for improvement in evaluating the odd zonal harmonics. There are gaps in the coverage in inclination at angles between 6° and 14°, between 16° and 28° and between 33° and 41°. Until these gaps are filled by the launch of suitable satellites,

the validity of the fitting of β in the empty regions will remain open to question.

Microearthquake Study of the Mid-Atlantic Ridge near 37° N, using Sonobuoys

IN view of the successful use of telemetering radio sonobuoys for detecting and locating microearthquakes in the Gulf of California¹, we carried out a similar survey of the Mid-Atlantic Ridge, in the region near latitude 37° N, during May and June of this year. Our object was to study the level of distribution of seismicity; in particular, we hoped to locate some earthquakes sufficiently accurately that we could associate them with local physiographic features, and draw conclusions about the present tectonic activity of this section of the ridge. Teleseismic study of the mid-ocean ridge suffers from two basic limitations: the epicentral locations are not sufficiently accurate to allow more than a general correlation of seismic activity with the median rift (where present) and with the transform faults offsetting the ridge segments², and it is not generally possible to locate earthquakes of magnitude less than about 4 (ref. 3). Ocean

bottom seismometers have also been used to study ridge seismicity, but the results to date have been fairly limited.

The study described here was undertaken as an ancillary programme on cruise 31 (WHOI TOW I) or RV Knorr (Woods Hole Oceanographic Institution). The main object of this cruise was a detailed survey of the area, using the Scripps Institution of Oceanography/Marine Physical Laboratory's deep-tow instrument package⁵. This, in turn, was part of a continuing intensive study of this section of the Mid-Atlantic Ridge (Project FAMOUS). As a result, the topography is well enough known to allow meaningful correlation with the seismicity.

The technique used was basically that described by Reid *et al.*¹ for the Gulf of California. Expendable sonobuoys⁶ were monitored by onboard recording equipment. The sonobuoy positions were found by firing explosive charges to determine their range from the ship. Whenever possible, we tried to maintain an array of at least three sonobuoys operating, with a spacing of a few kilometres. We obtained fifty-nine epicentral locations, out of 104 earthquakes recorded during 11 d of favourable recording conditions. More than half the locations have an estimated error of 2 km or less.

Figure 1 shows the record of a typical event at a distance of about 30 km. We follow the phase identification and nomenclature of Reid *et al.*¹. The P and S arrivals are the direct compressional and shear waves through the crust, and the T phase is interpreted as the wave travelling through the water layer from the epicentre. At distances less than about 10 km, S and T phases are not normally seen, and the observed phases are P and its reflections in the water column, designated P₁, P₂, and so on.

Fig. 1 Recording of a typical earthquake detected on sonobuoys. The epicentral distance is about 30 km. (This is not the original record but a replay off magnetic tape.)

Fig. 2 Cumulative number of earthquakes recorded against cumulative number of low-noise recording hours. The dashed vertical lines indicate the successive sonobuoy arrays.

The results are summarised in Figs 2 and 3. Figure 2 is a plot of cumulative number of earthquakes recorded against cumulative number of low-noise recording hours, and Fig. 3 shows the located epicentres superposed on a bathymetric contour map of the area. As Fig. 3 shows, the study area includes a ridge segment with a well defined median rift, 45 km long and averaging 7 km width. This is terminated by two fracture zones, designated fracture zone A (to the north) and fracture zone B (to the south), which offset the ridge from its continuations. Figure 2 also shows in which part of the area the sonobuoy arrays were placed. On the first leg of the cruise, during which the main survey of the rift took place, the weather was consistently poor, result-

Fig. 3 Map of the best located epicentres, superposed on a bathymetric map of the area. The tectonic interpretation shown is a simplified approximation. ●, Good locations (generally with less than 2 km error); ○, less reliable locations (up to about 5 km error). The star-like symbol at the west end of fracture zone A represents a swarm-type sequence of about seven recorded events.

ing in a noise level too high for effective recording. During the second leg, operations were concentrated on the fracture zones, particularly fracture zone A, and this is reflected in Fig. 2 and in the density of epicentres in Fig. 3.

The seismicity seems to be quite uniform in time (Fig. 2) and the same for both fracture zones. The sample of rift seismicity is not sufficient to allow firm conclusions to be drawn, but it seems lower than the fracture zone seismicity. Figure 2 has been compiled from the raw data, with no corrections for earthquake magnitude or for distance from the array. But we believe Fig. 2 is a fair representation of the seismicity, at least for the fracture zones. We have not attempted any individual magnitude estimates; the detection threshold for a nearby event is about $M=0$, and we estimate most of the earthquakes recorded to be between $M=0$ and $M=1$. In contrast to the Gulf of California or the Galapagos spreading centre, where microearthquake swarms seem to predominate^{1,7} there were only two or three swarm-like sequences⁸ recorded, consisting of up to seven closely spaced events. The microseismicity, at ten events per day, is comparable with that on active sections of the San Andreas Fault⁹, and is consistent with the number of teleseismically detected earthquakes occurring along this section of the Mid-Atlantic Ridge¹⁰.

Figure 3 demonstrates the excellent correlation of the seismicity with the fracture zones deduced from the topography. It clearly shows that most activity is restricted to the section of fracture zone between the rift segments, that is the section where transform faulting¹¹ is occurring. Along fracture zone B, the seismicity appears to delineate a simple transform fault, characterized by a narrow line of epicentres and narrow topographic notch (seen on the deep-tow data but not on the Fig. 3 map). Fracture zone A comprises a

broader region of deformation, with a number of fault scarps and grabens (R. Detrick, personal communication). Most of the computed fracture zone A epicentres, however, lie within 1 km of a straight line, well inside the location uncertainty, which we estimate to be less than 2 km in most cases. This suggests that only one fault plane may be presently active. The active transform faults, as delineated by the seismicity, seem to be narrow and linear, even on a small scale. They are also active over their entire length, even over short time intervals. They show the usual orthogonality to the ridge axis¹².

The junctions of the fracture zones with the median rift are characterized by topographic depressions. The deep-tow study showed that the depression at the junction of fracture zone A with the central rift is bounded on the north by a well defined fault scarp, which we interpret as the active transform fault. This scarp showed a high level of seismic activity, including the only located swarm, and we located one event on this scarp with particularly high accuracy (within 0.5 km). This suggests that active transform faulting continues well into the central rift valley, and hence, that the spreading centre plate boundary (or zone of intrusion), is itself a narrow feature within the central valley.

Because of the small sampling and, we believe, lower seismicity, there are hardly any reliable locations along the rift itself. Such evidence as there is suggests that the seismicity may be concentrated near the edge of the rift, and that there is essentially no activity outside the rift. This would be expected if normal faulting on the rift walls were the dominant source of rift earthquakes¹³. If the low microseismicity of the rift, particularly the low incidence of swarms, is real, then this is in sharp contrast to the Gulf of California and the Galapagos spreading centre, where the spreading segments are highly active^{1,7}. This might indicate less volcanic activity on this slower spreading ridge⁸.

We found it difficult to obtain accurate focal depths in this study, due to array limitations. In one case we found a focal depth of about 1 ± 1 km for a fracture zone A event. Other evidence, particularly the predominant T phase of many events, suggests an equally shallow source for most of the events recorded. In obtaining the epicentre locations, we have generally assumed zero focal depth and a P velocity of 5 km s^{-1} . This should not lead to appreciable errors in most cases. In general, the detailed seismicity and earthquake distribution seem to be in good agreement with current ideas on mid-ocean ridge plate tectonics.

We thank the Chief Scientists of the expedition, Drs B. P. Luyendyk, F. N. Spiess and J. D. Mudie, for accommodating and assisting this work and for allowing us to make use of the deep-tow data, and Dr J. D. Phillips for allowing us to use the bathymetric map of Fig. 3. This research was supported by National Science Foundation grants.

Location of Hydrogen Atoms in ADP by Neutron Powder Profile Refinement

NEUTRON diffraction is a powerful tool for the location of light atoms, especially hydrogen, because the neutron scattering power of these atoms is comparable to that of the heavier elements. In particular, the study of hydrogen bonding and its effect on the physical properties of molecular crystals is well suited to neutron diffraction techniques. Unfortunately, because of the relatively low flux of thermal neutrons available, even from the best reactors, rather large single crystals are required, together with expensively long periods of time for data collection. Even when large crystals can be grown, multiple scattering (extinction effects) introduce systematic errors which limit the precision with which atoms can be located. It would be important then, if some way could be found to eliminate the need for large single crystals and long periods for data collection.

The powder diffraction method solves some of these problems, but it is usually thought that neutron powder patterns contain too little information to allow the solution of any but the most simple crystal structures. I argue that provided we abandon the traditional method of structure refinement

Fig. 1 The [100] projection of the $\text{NH}_4\text{H}_2\text{PO}_4$ structure showing the two positions between which the hydrogen atom linking PO_4 groups can tunnel (after Tenzer *et al.*⁴).

Fig. 2 Observed and calculated powder profiles of deuterated ADP for 1.54 Å neutrons. The positions of the separate Bragg reflexions contributing to these profiles, which were obtained in 22 h on the PANDA diffractometer at Harwell, are marked along the 2θ scattering angle axis. The superlattice lines in the low temperature phase appear because the ordering of the O-H . . . O hydrogen atoms reduces the symmetry from $I4_2d$ at room temperature (a) to $P2_12_12_1$ at 77.4 K (b).

based on the measurement of structure factors, there is much more useful information in a neutron powder pattern than is immediately obvious.

Information is lost, of course, because the crystalline grains in a powder have all orientations; the intensity scattered into a particular direction is the sum of all reflexions having that particular Bragg angle. Because of the finite resolution of a diffractometer, this usually results in a very complicated diffraction pattern from which it is impossible to resolve individual reflexions and to obtain a set of structure factors. Rietveld¹ has shown that in this case it is best to refine the structure to fit directly the observed diffraction pattern, rather than to try to extract the structure factors as an intermediate step. Fortunately, because of the simple radiation spectrum and geometry of a neutron diffractometer, the shape of a single Bragg powder peak is known very precisely for every scattering angle: it is a Gaussian. The positions of all these peaks are fixed by the crystal lattice constants, and so the detailed shape of the entire pattern must be determined solely by the positions of the atom in the crystal lattice; these positions can be refined to obtain the best agreement between the calculated and observed diffraction pattern "profiles".

This profile refinement technique has proved very valuable for the structure refinement of inorganic materials^{1,2}, but now I apply it to more complicated crystals, especially to hydrogen bonded structures. ADP, ammonium dihydrogen phosphate ($\text{NH}_4\text{H}_2\text{PO}_4$) is a rather single example, but the hydrogen bonds are responsible for a very interesting structural transition which occurs at ~ 245 K in the deuterated material. The (H_2) hydrogen atoms have two stable positions, close to one or the other of two oxygen atoms in adjacent PO_4 groups⁴. At room temperature these hydrogen atoms have sufficient energy to tunnel between the two stable positions, and the average occupancy of both positions is $\frac{1}{2}$. When the temperature is lowered the hydrogen atoms are presumably caught in one or the other of these positions, but there is no random

* From observed ratios b/a , c/a : the neutron wavelength $\lambda=1.53 \text{ \AA}$ was not measured precisely.

In the low temperature antiferroelectric phase, these atoms are ordered on one of the two sites over which they are distributed in the room temperature paraelectric phase (see Fig. 3). The R factors are for separated structure factors, and the numbers in parentheses are the standard deviations for the parameters¹.

distribution; there seems to be an ordering of these hydrogen bonds which results in a distortion of the structure from tetragonal ($I\bar{4}2d$) to orthorhombic $P2_12_12_1$. This mechanism is similar to that found by Bacon and Pease³ to be responsible for the ferroelectric transition in KH_2PO_4 , but in the ammonium salt the transition is antiferroelectric. It is important to find the reason for this difference, but experiments on the low temperature structure of $\text{NH}_4\text{H}_2\text{PO}_4$ are difficult: the crystal shatters when passed through the transition because the different domains distort in different directions. This difficulty has held up the solution of the low temperature structure for twenty years.

This experimental problem does not exist for a powdered specimen. In Fig. 2 I show the diffraction pattern obtained in 22 h from 15 g of deuterated ADP, both above (a) and below (b) the transition temperature. The strong "super lattice" reflexions observed in the low temperature phase reflect the lowering of the symmetry which occurs when the deuterium atoms order on one or the other of the sites available to them, thereby distorting the whole structure. The solid lines in these diagrams represent the calculated profiles which best fit the observed points. In both cases, the fit approaches that expected for purely statistical errors in the count. The coordinates and vibrational amplitudes of all of the atoms in both structures have been obtained, but the structural transition can most simply be described if I refer only to the (H_2) hydrogen positions.

Fig. 3 Ordering of the deuterium atoms (H) on the hydrogen bonds between the phosphate groups, as proposed by Nagamiya⁵ and verified in the present experiment.

In Table 1 I give the coordinates obtained for the two equivalent hydrogen sites in the high temperature phase, when each is occupied for half of the time. In the low temperature phase, I find that the diffraction pattern can be explained if I assume that only one of these alternative positions is occupied. When the occupation numbers for the two positions were refined, starting with $\frac{1}{2}$ for both, the one approached unity while the other approached zero within the limits of uncertainty imposed by the data (1.0 ± 0.1). Figure 3 shows how these positions are taken up to produce a perfectly ordered arrangement of hydrogen bonds, but one in which there is no net dipole moment for the complete cell. This result confirms the ordering proposed by Nagamiya⁵. The PO_4 group at $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$, which was equivalent to that at (000) in the high temperature phase, becomes inequivalent in the low temperature phase because of this ordering of hydrogen atoms. These phosphate groups, and the ammonium groups too, are slightly distorted by this hydrogen atom ordering (the ammonium groups are displaced as well), but the resulting dipole moments cancel out over the entire cell and the low temperature structure is antiferroelectric rather than ferroelectric as in KH_2PO_4 .

Finally I note that the profile powder method is a technique for structure refinement: it is not intended to compete with methods such as those based on Fourier techniques for the solution of structures about which very little is known. But with neutron diffraction we are almost always trying to refine the details of a structure which has already been solved approximately by X-ray or other techniques—finding more precise positions for the atoms, especially those of hydrogen and the lighter elements, measuring magnetic moments, nuclear and magnetic disorder, defect structures, atomic vibrational amplitudes and so on. For these structure refinement problems the profile refinement of neutron powder patterns often has many advantages over single crystal method. New designs for neutron powder diffractometers, giving greatly increased resolution and intensity, will allow larger structures to be studied with this technique.

I thank Dr B. T. M. Willis for encouragement and Dr H. M. Rietveld of the Reactor Centrum Nederland for a copy of his original profile refinement computer program.

BIOLOGICAL SCIENCES

Suppression of Mouse Antibody Producing Spleen Cells by Various Interferon Preparations

POLYRIBOINOSINIC acid: polyribocytidylic acid [poly (rI)-poly (rC)], endotoxin, polycarboxylate plastics or polysaccharides, and other polyanions induce interferon production (see reviews ref. 1 and 2). They also enhance antibody production^{3,4}, cell-mediated immunity⁵, and reticulo-endothelial activity^{4,6}. It is not yet clear whether or not any of these latter effects are mediated through the action of interferon.

Recently, mouse interferon preparations from several different sources have been shown to enhance phagocytic activity in peritoneal macrophages cultivated *in vitro*⁷. Also, many reports have shown antitumour activity in interferon preparations both *in vivo* and in cell culture (see review ref. 2).

Attempts have been made to measure the effects of interferon preparations on *in vivo* antibody production, but these studies demonstrated either no effect⁸ or variable effects, including modest stimulation or inhibition⁹. Large amounts of interferon are required to simulate *in vivo* the circulating interferon levels produced by inducers such as poly (rI)-poly (rC), and past work has been restricted to interferon levels considerably lower than those obtained with inducers. Our studies were conducted with potent interferons, and measured the effects of a variety of interferon preparations on the number of mouse spleen cells producing antibody to sheep red blood cells (SRBC) during primary immunization. Interferon was administered in several large doses over 3 h, giving a reasonable simulation of both the levels and the time course of circulating interferon following poly (rI)-poly (rC)-administration.

Four different interferon preparations, stimulated by Newcastle Disease virus (NDV), were used: (1) pressure dialysed L₉₂₉ cell supernatant, (2) pressure dialysed C243-3C cell¹⁰ supernatant, (3) mouse serum, and (4) L cell interferon which was purified by affinity chromatography using anti-mouse interferon antibody to a purity of 1.96×10^8 units mg⁻¹ protein¹¹.

When 100 µg of poly (rI)-poly (rC) was given either 2 d or 4 d before antigen, a two-fold increase in the number of antibody producing spleen cells assayed 6 d after antigen administration occurred (Table 1). To determine the amount of interferon necessary to successfully simulate the circulating interferon levels induced by poly (rI)-poly (rC), two different doses of interferon were administered, sera were taken at various times, and then the interferon titres compared to those achieved after intravenous (i.v.) administration of 100 µg of poly (rI)-poly (rC). In one case approximately 1.8×10^5 units of L₉₂₉ cell interferon were administered i.v. in four divided doses over a 4 h period, in the other, approximately 4.2×10^4 units were similarly given. As can be seen from the results plotted in Fig. 1, the larger dosage schedule resulted in serum interferon levels approximately equal to that achieved by poly (rI)-poly (rC) while the lower dosage level did not achieve adequate serum levels to simulate the interferon production of the dose of poly (rI)-poly (rC) necessary to simulate an increase in the number of antibody producing spleen cells.

When 1.8×10^5 units of L₉₂₉ cell interferon were thus given 2 d before antigen (SRBC), at a time when poly (rI)-poly (rC) caused a marked enhancement of the number of antibody producing spleen cells as assayed 6 d after antigen administration (Table 1), we were surprised to note a sharp depression in the number of antibody-producing spleen cells to 16% of that in uninjected control animals.

This experiment was repeated several times with different interferon preparations. As can be seen in Fig. 2 and Table 1, as the interferon titre increased, the degree of depression increased, giving a sigmoidally shaped dose response curve characteristic of the antiviral action of interferon. Doses of over 1×10^5 units of interferon gave marked depression (16% of control), while doses between 5×10^4 units and 1×10^5 units showed an intermediate degree of depression with a greater degree of variability. Doses of less than 5×10^4 units showed no measurable depression.

Fig. 1 Comparison of serum interferon attained after i.v. injection of various doses of interferon with that attained after induction by poly (rI)-poly (rC). Interferon titres were measured with a plaque reduction assay on mouse L₉₂₉-cell monolayers employing bovine vesicular stomatitis virus (VSV), Indiana strain, as a challenge virus²⁰. The interferon titre corresponded to the reciprocal of the highest dilution of sample which reduced virus plaque formation by 50%. Titration of the 6,000 unit mouse interferon standard distributed by the National Institutes of Health revealed a unitage of 2,490 units per vial in this assay. Serum levels of interferon attained in 6-week-old Swiss-Webster mice after intravenous administration of 100 µg of poly (rI)-poly (rC) at time 0 (○—○). Serum levels of interferon attained after intravenous administration of L₉₂₉ cell interferon (titre 5.2×10^4 units), 1.0 ml at 1, 2, and 3 h and 0.5 ml at 4 h (□—□), and after L₉₂₉ cell interferon (titre 1.2×10^4 units) at the same times and amounts (■—■). Clearance curves are extrapolated to expected concentrations at zero time after injection.

To test whether volume of injection or the presence of other non-interferon substances may be responsible for this effect, two preparations of supernatant from uninduced L₉₂₉ cell monolayers and one preparation of mouse serum from uninduced mice were inoculated in the same volumes as were the interferon preparations with no significant deviation from control values (Fig. 2). These preparations were in all respects processed and concentrated similarly to their corresponding interferon preparations, and all titred at less than 10 units of interferon. In addition, a portion of one batch of C243-3C cell interferon preparation was exposed to trypsin (0.25 mg ml⁻¹) for 1 h at 37° C and another heated to 56° C for 1 h. These preparations along with an untreated portion were inoculated into a series of mice. The untreated portion showed the usual immuno-

Table 1 Effect of Various Interferon Preparations on Antibody Producing Cells

Substances	Dose	Day of administration relative to antigen	Antibody producing cells* (% of mean control level)		No. of animals	Significance of difference from control
			Mean	Range of $\pm$ s.d.		
Poly (rI)·poly (rC)	100 μ g	2 d before	209%	175% to 251%	10	$P < 0.001$
Interferon, all types†	100 μ g	4 d before	170%	137% to 210%	7	$P < 0.05$
	$> 1 \times 10^5$ units	2 d before	16%	12% to 20%	9	$P < 0.001$
	4×10^4 units	†	76%	62% to 95%	8	$P < 0.11$

* Statistical analysis of the results was carried out by linear regression analysis on the natural logarithms of the observed data, assuming orthogonality between any day-to-day variation in the baseline and experimental effects. The geometric (logarithmic) mean $\pm$ s.d. is given as a percentage of the mean control value. In the computer program used for this analysis, the reported s.d. and confidence limits of the experimental groups are expanded to include the s.d. of the mean control value. Duplicate assays were conducted on each spleen.

† Two animals received L_{929} cell interferon, six C243-3C cell interferon, and one mouse serum interferon.

‡ Five animals 2 d before, one animal 3 d before, and two animals 4 d before.

Fig. 2 Relationship of interferon dose and number of antibody producing spleen cells. Animals were sensitized to SRBC antigen by intravenous administration of 2×10^7 SRBC in 0.5 ml saline. Antibody-producing capability was measured by the number of spleen cells producing antibody to SRBC 6 d after antigen administration. Antibody-producing cells were assayed by the plaque technique²¹ as extended for use on microscope slides²² with modifications as previously described⁴. Various doses of interferon were administered 2 d before administration of antigen (SRBC). The number of nucleated spleen cells producing antibody to SRBC was assayed 6 d after antigen administration and expressed as a percentage of the number of antibody producing spleen cells in uninjected controls. All determinations shown represent the mean in at least two animals. Ranges shown are $\pm$ s.d. Two uninduced control preparations containing less than 10 units of interferon were also used. One consisted of pressure dialysed supernatant of L_{929} cell tissue culture medium (●), and the other of serum from untreated mice (▲). Interferon preparations from four sources were used, all induced with NDV. One from L_{929} cells and pressure dialysed 5 to 50-fold (○) (ref. 18), one from C243-3C cells and pressure dialysed 20-fold (×) (ref. 10), one from mouse serum 10 h after injection of NDV (△), and one purified on an anti-interferon affinity chromatography column (□) (ref. 11). Five days of pH 2 treatment was used to inactivate NDV in all interferon preparations and no residual interfering activity as titred in human neonatal fibroblasts was noted in any preparation.

depressant activity (17% of control), while the inactivated preparations showed only activity consistent with their residual antiviral activity (Table 1). To check the species specificity of the depressant activity, 1×10^5 units of human leukocyte interferon were administered to mice with the result that no significant decrease in the number of antibody producing spleen cells was observed (Table 1).

At first the differing effects of interferon inducers such as poly (rI)·poly (rC), which increases the number of antibody producing spleen cells, and interferon preparations which decrease the number of antibody producing spleen cells, seem paradoxical. Recent findings, however, do provide a possible explanation; in addition to inhibition of multiplication of tumour cells, interferon preparations inhibit the multiplication of tissue culture cells in both continuous cell lines^{12,13} and primary cell cultures^{14,15}. Also, interferon preparations have been reported to inhibit DNA synthesis in mouse lymphocyte suspensions stimulated by phytohaemagglutinin¹⁶, and to inhibit proliferation of transferred spleen cells and the ability of these transferred lymphocytes to become sensitized to host alloantigens as assayed by an *in vitro* cytotoxic assay system¹⁷. In view of these findings that interferon depresses cell multiplication, inhibits DNA synthesis in lymphocytes, and otherwise blocks T lymphocyte function, it is not surprising that we should now find that interferon inhibits B lymphocyte expression in response to primary antigen stimulation.

Our results may form grounds for concern with regard to the use of interferon preparations in the treatment of viral infections in humans. It should be noted, however, that circulating interferon titres of the level required to produce these effects are produced transiently during a variety of systemic viral infections in the mouse. Also, concerning the possible clinical usefulness of exogenous interferon, it is important to compare the doses which we find to inhibit antibody producing cells in the spleen with that required to prevent various viral infections. The immunosuppressive doses are approximately 10 to 100-fold greater than that required to prevent a lethal cytotoxic virus infection¹⁸ or virus induced neoplasm¹⁹ in the same species. Previous observation⁹ of an immunosuppressive effect at one twentieth the dosage required in our study could not be confirmed, and further study is needed to elucidate the discrepancy between these two results.

Changes in the Incorporation of Different RNA Precursors into the Maternal Liver during Pregnancy

DIFFERENT RNA precursors have been utilized to label foetal and maternal RNA *in vivo* with varying results^{1,2}. Recently ³H-cytidine has been shown to effect the highest level of radioactive incorporation into both the maternal and foetal RNA³. The work reported here was undertaken to compare the incorporation of three separate RNA precursors into the rat maternal liver serially throughout gestation; thus, differences in incorporation that may develop with pregnancy among the individual precursors can be compared directly.

Dated pregnant Sprague-Dawley rats (Zivic Miller, Pittsburgh) weighing 200–420 g were used. Two hours after

Fig. 1 Incorporation of (A) ³H-uridine (28 Ci mmol⁻¹), (B) ³H-cytidine (6 Ci mmol⁻¹), and (C) ³H-orotic acid (11 Ci mmol⁻¹) into maternal liver 2 h after injection. Bars represent standard error of mean. 0 d pregnancy indicates studies on young male rats. p.p., 24 h post-partum; ○, acid-soluble counts; ●, acid-insoluble counts.

intraperitoneal injection of isotopes (10 μ Ci per 100 g of body weight), the animals were killed by cervical dislocation. A 2.0 g sample of the maternal liver was homogenised in 9 volumes of cold 0.1 M sodium acetate buffer, pH 5.0, using a Potter-Elvehjem homogeniser. One-tenth volume of 50% trichloroacetic acid was added, stirred and centrifuged. The precipitate was washed twice with 5% trichloroacetic acid. A 0.5 ml sample of the pooled washings and the supernatant was placed in 10.0 ml of Bray's solution to measure the level of radioactivity using a liquid scintillation counter. The precipitate was hydrolysed for 15 min in 10 ml of 10% trichloroacetic acid in a boiling water bath, cooled and centrifuged at 10,000g for 10 min. Using 0.5 ml from the resulting supernatant the radioactivity of the acid-insoluble counts was determined in Bray's solution.

Fig. 2 Incorporation of ^3H -uridine (lower curve), ^3H -cytidine (upper curve) and ^3H -orotic acid (middle curve) into the maternal liver of 16-d pregnant rats with varying specific activities. The experiments were conducted as described in Fig. 1. The total volume of the precursor was kept constant through the study. $\circ$, Represents the specific activity used in experiments shown in Fig. 1.

The 2 h post-injection period was selected since ^3H -cytidine reached maximum incorporation at this time in accordance with a previous study³; whereas ^3H -uridine yielded a consistent and steady level of radioactive incorporation during the same time. The identical 2-h interval was maintained with ^3H -orotic acid only for purposes of comparison since ^3H -orotic acid continued to be incorporated for a longer time.

Figure 1 clearly shows the marked differences in the incorporation of isotopically labelled uridine, cytidine and orotic acid. The non-pregnant rats in this series designated as 0 d represent male rats (170–190 g) because of the wide variations observed from using virgin rats, especially with ^3H -uridine. Additional experiments performed on animals 48 to 72 h after delivery yielded results similar to those noted in the 24 h post-partum group shown in Fig. 1. Thus, the post-partum values may be most representative of the non-pregnant state for comparison with pregnancy. Every point in the figure represents an average of two to three separate animal experiments; when considerable scatter of values was obtained, especially towards the end of pregnancy, an additional six to eight animals were studied to determine the standard error of the mean. Note that early in pregnancy, uridine displayed decreased incorporation while cytidine and orotic acid had values comparable with the post-partum group. Although the orotic acid was incorporated to an unusually high degree among the male rats, cytidine is the most effective during pregnancy, confirming an earlier report³. Uridine was the least efficient precursor in both the pregnant and non-pregnant states, and further experiments revealed no changes in uridine

kinase in the maternal liver during pregnancy. The acid-soluble counts, although graphed only with the cytidine studies, in all cases mirrored the changes observed in the acid-insoluble counts, but the actual values were slightly higher. However, the most dramatic and consistent result was the sharp decrease in the incorporation of all precursors on the twenty-first day of pregnancy, just before parturition. Within 24 h post-partum the level of incorporation returned to earlier pregnant or non-pregnant values.

Fig. 3 The incorporation of ^3H -cytidine and ^3H -uridine into the nucleus and cytoplasm of maternal liver during various stages of pregnancy. A and C, Nuclear acid-insoluble counts (uridine); B and D, cytoplasmic acid-insoluble counts (cytidine). Non-pregnant rats represent young male animals. At specific times after intraperitoneal injection of isotopes (10 μCi per 100 g of body weight), the animals were killed. From 4.0 g of liver, 25% homogenate was prepared with 0.1 M sodium acetate buffer, pH 5.0, using Tri-R Homogenizer for ten strokes at 1,200 r.p.m. The homogenate was filtered through four layers of cheese cloth and the nuclear fraction was isolated as a pellet by centrifugation at 700g for 20 min. The nuclear and cytoplasmic preparations were treated with an equal volume of 10% trichloroacetic acid and washed once with 5% trichloroacetic acid. The resulting precipitates were treated and counted as acid-insoluble radioactive counts as described earlier in Fig. 1. $\circ$ — $\circ$, 8 d; $\circ$ — $\circ$, 18 d; $\bullet$ — $\bullet$, 21 d; $\bullet$ — $\bullet$, non-pregnant.

In approximately a quarter of the rats studied, an additional procedure included measurement of radioactivity in the blood. One and a half hours after injection of the labelled precursor, the animals were sedated by intramuscular injection of sodium pentobarbital (30 mg. kg⁻¹). Rats were anaesthetised in an ether chamber just before death 2 h after injection and 3.0 ml of blood was obtained by a direct cardiac tap using a 20 gauge needle and a heparinised syringe. Aliquots of 0.1 ml of plasma were placed in 10.0 ml of Bray's solution to determine radioactivity. The maternal liver was homogenised and prepared as described earlier. The level of blood radioactivity measured in the plasma was relatively constant throughout pregnant and non-pregnant animals with only a slight decrease at 21 d. With orotic acid and uridine the radioactivity measured 40,000 to 55,000 c.p.m. ml⁻¹ of plasma; whereas, cytidine showed only 9,000 to 11,000 c.p.m. ml⁻¹ of plasma.

Figure 2 illustrates the differences in incorporation of 16-d pregnant rats using precursors with varying specific activities. Orotic acid showed a slight rise in radioactivity with increasing specific activities, but cytidine exhibited a marked increase. In direct contrast, uridine showed no change with even greater alterations in specific activities suggesting a rapid saturation of its system. Although the actual measured radioactive counts were considerably lower, a similar pattern of response was observed in 21-d pregnant rats with all three precursors.

Figure 3 demonstrates the marked differences in the incorporation of ³H-uridine and ³H-cytidine into the nuclear and cytoplasmic portions of the liver during various stages of pregnancy. Although the actual amount of radioactive labelling is relatively small by comparison, ³H-uridine is incorporated rapidly into both the nuclear and cytoplasmic RNA and then falls off within 30 min. The 21-d pregnant rat shows poor uptake of radioactivity throughout the 2 h period of observation. The incorporation of ³H-cytidine differs in that the isotopic incorporation in both the nucleus and cytoplasm increases during the 2 h period, in a manner similar to that observed using labelled orotic acid. The 8 and 18-d pregnant rats reveal enhanced labelling compared with the non-pregnant rat, but the 21-d pregnant rat displays

Table 1 Comparison of Specific Activity of Liver RNA Polymerases in 16-d and 21-d Pregnant Rats

	16-d pregnant rats	21-d pregnant rats
	Mg ²⁺ -activated	
Nuclear	131	253
Nucleolar	158	161
Extranucleolar	2,199	1,306
	Mn ²⁺ (NH ₄) ₂ SO ₄ -activated	
Nuclear	116	220
Nucleolar	217	165
Extranucleolar	2,716	1,623

Nuclei were isolated from liver homogenate according to Widnell and Tata⁴, and nucleolar and extranucleolar (nucleoplasmic) suspensions were prepared as described by Yu and Fiegelson⁵. The RNA polymerase assay was essentially the method of Weiss⁶. The reaction mixture contained 50 µmol of Tris-HCl buffer, pH 8.5; 2.5 µmol of magnesium chloride, 3 µmol of sodium fluoride and 10 µmol of cysteine; 0.3 µmol each of GTP, CTP and ATP and 0.015 µmol of UTP; 2.0 µCi of 5-³H-UTP (Schwarz-Mann, 14.0 Ci mmol⁻¹) and 0.1 ml of enzyme suspension. For the ammonium sulphate assay 2.0 µmol of MnCl₂ and 0.2 mmol of (NH₄)₂SO₄ were used instead of MgCl₂ and the pH of the buffer was 7.5 (ref. 7). After incubation for 15 min at 37°C the reactions were stopped, adding 0.10 M sodium pyrophosphate containing RNA and bovine serum albumin⁸. The RNA was collected on Whatman GF C filters and radioactivity measured with liquid scintillation counter using 10.0 ml Bray's solution. RNA determinations were done according to Fleck and Munro⁹. Values represent an average of three determinations and indicate pmol of UMP incorporation per mg DNA.

a markedly depressed level of incorporation as noted in the ³H-uridine experiments.

To exclude the possible effects of changes in the intra-peritoneal absorption of isotopes, the three labelled precursors were administered intravenously through the tail vein to another group of 16-d and 21-d pregnant animals. Again a comparable labelling of the 16-d pregnant and the depressed incorporation of the 21-d pregnant rats were noted as the results show in Fig. 1.

Table 1 summarises our studies on the nuclear, nucleolar and extranucleolar DNA-dependent RNA polymerases from the livers of 16-d and 21-d pregnant rats. The results indicate that there is no drastic decrease in the specific activity of DNA-dependent RNA polymerases in the 21-d pregnant rat in spite of the marked depression in the incorporation of RNA precursors. There is a measurable drop only in the extranucleolar DNA-dependent RNA polymerase.

The specific causes for the changes in the incorporation of the various RNA precursors during pregnancy remains unresolved although endocrine influences must play a dominant role. The work reported here, however, clearly indicates that pregnancy and the duration of pregnancy have profound effects on the degree of RNA incorporation with different RNA precursors.

Slightly Deleterious Mutant Substitutions in Evolution

RECENT advances in molecular genetics have had a great deal of influence on evolutionary theory, and in particular, the neutral mutation-random drift hypothesis of molecular evolution^{1,2} has stimulated much interest. The concept of neutral mutant substitution in the population by random genetic drift can be extended to include random fixation of very slightly deleterious mutations which have more chance of being selected against than of being selected for^{3,4}. If this class of mutant substitution is important, we can predict that the evolution is rapid in small populations or at the time of speciation⁵. Here I shall organize the observed facts which indicate that this class is in fact important.

Fitch and Margoliash⁶ have shown that the frequency of double fixation of mutants in a leg of their cytochrome c phylogenetic tree is higher than predicted from chance. The

most plausible interpretation is that the first mutant is slightly deleterious and that the second compensates for the first. This interpretation makes Fitch's concept of the covarion⁷ most easily understood. If the first mutant disturbs very slightly the normal function of the molecule, there are probably many ways of compensating, and so the first mutant provides a new possibility for evolutionary change. This is considered to correspond to Fitch's observation of unstable covarions⁷.

The evolution of tRNA follows the same pattern. It is known that evolution is more rapid in the paired region than in the non-paired region of tRNA⁸. In most tRNAs, the paired region is almost exactly paired, therefore there must have been coupled substitutions in evolution as first mentioned by Jukes⁹. Dayhoff and McLaughlin⁸ state "this could be explained by an oscillatory sequence of evolutionary events, involving first a single base change that weakens the bonding, followed by a second change which restores the hydrogen-bond pairing". It is hard to conclude from this that each sequence has evolved so as to fit better into its environment. It indicates rather that the first substitution is slightly deleterious. This idea can be extended to other protein molecules, particularly if the polypeptide-folding mechanisms are important, as discussed by Barnard *et al.*¹⁰. Any amino acid substitution of a well organized molecule is likely to disturb the organization, but once it spreads in the population by random drift, it opens the way for further evolutionary change.

This hypothesis is compatible with a different point of view, that is, frequency distribution of multiple alleles detected by electrophoresis. Several investigators have been trying to prove or disprove the neutral theory of protein polymorphisms by looking at the pattern of allelic distribution^{11,12}. In such attempts, it is usually assumed that every mutant appearing in the population is one not pre-existing, that is to say, the so called "infinite allele model" of Kimura and Crow¹³ has been used extensively. The convenient statistics often used in the analysis are the effective number of alleles (n_e ; reciprocal of the sum of squares of allelic frequencies) and the actual number of alleles observed (n_a). Recently, Yamazaki and Maruyama¹⁴ made an extensive compilation and statistical analysis of published data on enzyme polymorphisms. In particular, they showed that the average ratio of the effective to the actual number of alleles (n_e/n_a) from the observed enzyme polymorphisms agrees well with the neutral hypothesis according to Kimura and Crow's infinite allele model. Here the ratio, n_e/n_a , represents a sort of evenness of allele distribution and, the higher the ratio, the more uniform the distribution expected. But this model seems to be inappropriate for electrophoretically detectable polymorphisms, for this method can only detect a difference in the electric charges of molecules as discrete bands on the gels. In fact Bulmer¹⁵ noticed non-random arrangements of electrophoretic bands of common and rare alleles. In view of these points, Maynard Smith¹⁶ and Kimura and Ohta¹⁷ have suggested that the model of stepwise allele production is more appropriate. Using this mutational scheme but assuming an infinite number of possible states, we have shown that the effective number of neutral alleles maintained in a finite population becomes, $n_e = \sqrt{(1 + 8N_e v)}$, where N_e is the effective population size and v is the mutation rate per gamete¹⁸. When $N_e v$ is large this formula gives a smaller effective allele number than that predicted by Kimura and Crow's model. Furthermore, the frequency distribution of multiple alleles is influenced significantly. We have performed extensive Monte Carlo experiments and have shown that the ratio of the effective to the actual number of alleles (n_e/n_a) is larger in the step allele model, particularly when n_a is large (T. O. and M. Kimura, unpublished). Then the agreement between the observation and Kimura and Crow's model shows that there exist more rare alleles than expected from the strict neutral hypothesis. From this, I conclude that rare alleles are on the

Table 1 Relationship between Substitution Rate in Small Populations and Equilibrium Frequency in Large Populations of Slightly Deleterious Mutations

Homozygous disadvantage	Equilibrium frequency in large populations	Rate of substitution in proportion of the completely neutral case	
		$N_e = 10^2$	$N_e = 10^3$
Recessive deleterious			
10^{-2}	0.032	0.43	0.8×10^{-7}
10^{-3}	0.1	0.94	0.43
10^{-4}	0.32	0.99	0.94
Semidominant deleterious			
10^{-2}	0.002	0.31	0.5×10^{-7}
10^{-3}	0.02	0.90	0.31
10^{-4}	0.2	0.99	0.90

The mutation rate is assumed to be 10^{-5} .

average selected against. The alleles, which can increase their frequency up to several per cent in very large populations like *Drosophila* species, can replace the previous allele in small populations by random drift.

O'Brien *et al.*¹⁹ reported that the "null" alleles at the α -glycerophosphate dehydrogenase-1 locus of *Drosophila melanogaster* are deleterious. As their null alleles were induced by EMS, they may be different from those observed in low frequencies in natural populations. It is likely, however, that the null alleles are generally deleterious. They can replace the previous allele in a bottleneck population. Vitamin requirement is in fact considered to be the result of such procedures. King and Jukes⁹ noticed that lack of vitamin C is always associated with the kind of food and they consider that, when selective constraints are reduced, the genes for vitamin C have deteriorated.

As an example, suppose that the homozygous disadvantage of the recessive deleterious mutant is 10^{-4} . If the mutation rate is 10^{-5} , the equilibrium mutant frequency is 10% in large populations. By using Kimura's²⁰ formula for the fixation probability of mutant genes, the rate of substitution of this slightly deleterious mutant becomes 0.43×10^{-5} per generation if the effective population size is 10^3 . This corresponds to 43% of the substitution rate of the strictly neutral case. Table 1 illustrates such examples in terms of the proportion of the substitution rate of the completely neutral case.

I have previously suggested the possibility of slightly deleterious mutant substitutions in cistrons in view of the apparently contradictory observation of generation-dependent DNA evolution against year-dependent cistron evolution⁴. Together with the supporting observations presented here, I suggest that very slight genetic deterioration might play an important role in molecular evolution. Here, organization at a much lower level in each molecule or in several interacting molecules could provide a clue to understanding the evolutionary change at the molecular level, rather than cohesive interaction of the pool often postulated by orthodox neo-Darwinism²¹. It seems from the report of Mukai *et al.*²² that there is no evidence that alleles at different loci constitute such interaction systems or "super genes". I thank Dr M. Kimura for discussions.

Antitumour Activity of Iodine in Acidic Medium with Calcium

THE basal metabolism is increased in many patients with lymphatic and myelogenous leukaemia. Elevated levels of plasma iodine have been found in various leukaemic cases, possibly indicating involvement of the thyroid gland¹. It is thought that at lower pH values there is more free iodine, and so greater penetrability into cells and greater iodine activity². Iodine fixation by human leukocytes requires energy³. Iodine alters the redox state of the cytoplasm and mitochondria, because the couple $2\text{I}^- \rightarrow \text{I}_2 + 2\text{e}^-$ has a rather high redox potential: +0.535 V; iodine seems to be one of the oxidizing agents which can be used for ATP formation⁴. Flavin is the most likely oxidizing agent for a couple with such a higher redox potential⁵.

The importance of calcium ions in controlling the permeability of cells⁶ and in regulating cellular activity⁷ has been established. The penetration of isolated ascites tumour cells by calcium ions depends on the metabolic state of the cells⁸; calcium accumulation, like iodine accumulation, requires energy and alters the redox state of the respiratory chain components.

It has been suggested that iodine in acidic medium with calcium has antitumour activity (L. Heinonen, personal communication). We therefore studied the effect of these substances against myelocytic chloroleukaemia⁹. This leukaemia was induced in 2 to 3-week-old Sprague-Dawley and Wistar rats by intraperitoneal or subcutaneous inoculation. Chloroleukaemic cells were suspended in physiological saline and 0.1 ml of the cell suspension, containing 10,000–20,000 cells, was injected into the rats. Survival time, histological examination and lactic acid dehydrogenase (LDH) activity were used to evaluate antitumour activity.

Treatment was started 24 h after the intraperitoneal inoculation by giving each rat about 500 μg of iodine daily as a 5% iodine-ethanol solution in cultured milk. Fourteen days after the inoculation the treatment with iodine was continued by subcutaneous injection. Treatment of the subcutaneously induced local tumours was by subcutaneous injection of iodine, starting about two weeks after inoculation, when the tumour was clearly visible and was usually about 2 cm $\times$ 3 cm, sometimes larger. The subcutaneous injections consisted of 500 μg of iodine in ethanol solution mixed with 1 ml of liver extract (Pernaemon forte, N.V., Organon, Oss, Netherlands). Immediately afterwards 1 ml of calcium gluconolactobionate solution (about 9 mg Ca^{2+}) (Calcium Sandoz, Sandoz AG, Basel, Switzerland) was injected intramuscularly. The injections were made once (intraperitoneally inoculated rats) or twice (subcutaneously inoculated rats) daily. Eleven days after

inoculation the intraperitoneally inoculated rats were injected with 25 mg of thiamine chloride (Neuramin forte, Orion Ltd., Espoo, Finland).

The rats' food consisted of vegetables, including cabbage and carrots, and fresh liver, with 3 mg riboflavin (Orion Ltd., Espoo, Finland) per rat per day. The control rats were given all the nutrients, liver extract, calcium and vitamins but not iodine.

Tissue samples were taken at autopsy not only from the visible tumours but also as a routine procedure from liver, spleen, kidney, lung, heart and bone marrow. After fixation in formalin the tissue samples were cut into sections 6 μm thick and stained with haematoxylin-eosin. The smear samples of femoral bone marrow were stained by the May-Grünwald-Giemsa method. The preparations were examined under a light microscope. LDH activity was estimated by measuring the extent of oxidation of NADH (at 340 nm).

Table 1 shows the effect of treatment on the survival time of the rats bearing a tumour inoculated intraperitoneally or subcutaneously. The index $T/C \times 100$ [(mean survival time of treated rats)/(mean survival time of untreated control rats) $\times 100$] was calculated to be >415 for the intraperitoneally inoculated rats. This is three to four times higher than the ratio reported by other workers^{10–12}. Our result might have been even better if the iodine administration had been by injection from the start of the experiment, as we found that the rats did not drink all of their iodine-containing cultured milk. The index was not calculated for the subcutaneously inoculated rats because the tumours had disappeared before the rats were killed (Tables 1 and 2). The average survival time

Table 1 Influence of Iodine Treatment on Survival Time

* C, Mean survival time of untreated control rats (f–k) = 11 d and of untreated control rats (XI–z) = 34 d.

† Rat II received iodine in cultured milk during the whole experimental period.

‡ Rat q received a more concentrated iodine-liver extract daily (1,000 to 4,500 μg of iodine ml^{-1}). The tumour underwent alteration to fatty necrosis.

of the control rats inoculated subcutaneously was 34 d from inoculation, somewhat longer than the survival time reported by Rytömaa and Kiviniemi¹³. All the five rats with local tumours became healthy after iodine treatment, and eight out of the total number of ten treated rats recovered, whereas eight out of the nine untreated control rats died.

Table 2 Effect of Treatment on the Size of Subcutaneously Induced Tumours

Rat	Diameter of tumour at beginning of treatment (cm)	Fate of tumour
Treated rats		
II		Complete disappearance in 14 d
q	2.8*	Transformation to fatty necrosis
r	2.0†	90% reduction in 2 d, complete disappearance in 3 d
s	1.5	Complete disappearance in 2 d
v	2.5	Complete disappearance in 3 d
Untreated control rats		
p	2.8	Growth ceased after 5 d
j	2.8	Growth continued
XI	1.5	Growth continued

* This tumour was treated by pouring over the tumour a large amount of iodine in liver extract, followed by the calcium solution.

† Two subcutaneous inoculations resulted in two tumours that grew together over the neck for a length of 4 cm.

The histological findings are presented in Table 3. Leukaemic infiltrations were found in only two of the ten treated rats. In the untreated group of eight rats there was tumour tissue in seven animals. Recovery was 100% from subcutaneously induced tumours and 60% from intraperitoneally induced tumours. One local large tumour (rat q) was treated by pouring over the tumour a large amount of iodine in liver extract, followed by the calcium solution. In its histological examination only fatty necrosis was seen. During the recovery of the treated rats the number of erythrocytes, the haemoglobin value, and the packed cell volume attained normal levels.

Elevated LDH activity has been found in a variety of tissue tumours and in acute and chronic myelocytic

leukaemia¹⁴. We measured the LDH activity in the pooled peripheral blood of treated rats (Table 4). In the rats with subcutaneous tumours the activity of LDH decreased during the treatment and was close to, though still above, the control value for normal healthy rats at the end of the treatment. The two leukaemic rats which did not recover are presumably the source of the elevated value in the pooled samples. The effectiveness of iodine in lowering LDH activity may be due to the fact that iodine rapidly oxidises the SH groups of LDH¹⁵, inhibiting the enzyme activity.

Table 4 LDH Activity in Peripheral Blood During the Treatment

Form of leukaemia	Stage of treatment			Duration of experiment (d)
	Beginning (before treatment)	Middle	End	
Intraperitoneally inoculated	8,000 (<i>n</i> =0)	6,490 (<i>n</i> =3)	4,630 (<i>n</i> =11)	5
Subcutaneous tumour	2,140 (<i>n</i> =0)	460 (<i>n</i> =10)	860 (<i>n</i> =16)	16
Normal healthy rats	720 (<i>n</i> =0)		650 (<i>n</i> =0)	16

n, No. of treatments.

LDH activity is given in Wroblensky units per ml.

Four rats on average were used for each determination.

The average body weight of the intraperitoneally inoculated and treated rats increased gradually from 30 g to 195 g in the month following inoculation, while the untreated rats showed only a small increase in weight (22 g) during their lifetime. After the disappearance of the local tumours from the subcutaneously implanted rats, their weight increased normally.

From these results it can be concluded that iodine in acidic medium with calcium has a remarkable activity against myelocytic chloroleukaemia. Iodine may act on the electron transport chain: mitochondria in tumour cells differ morphologically and functionally from normal cells. Most suggestions for the mechanism of action of anti-tumour agents have involved inhibition of DNA and protein synthesis, whereas we suggest that iodine acts by changing the redox state inside the cell.

We are grateful to Dr T. Rytömaa, Department of Pathology, University of Helsinki, for advice and for his gift of inoculated rats.

Vitamin D-induced Synthesis of mRNA for Calcium-binding Protein

THE discovery that vitamin D must first be converted into the metabolites 25-hydroxycholecalciferol¹ (25 OH-D₃) and 1,25-dihydroxycholecalciferol² (1,25(OH)₂-D₃) before calcium absorption across the small intestine is enhanced has radically changed existing ideas as to the mode of action of vitamin D. Indeed, it is now well established that the most active metabolite of vitamin D for calcium absorption, 1,25(OH)₂-D₃, is produced solely by the kidney³ and that its production and secretion are under very fine endocrine control. This finding, together with the observation that 1,25(OH)₂-D₃ is specifically located in the nucleus of the target cell⁴ and the apparent involvement of RNA and protein synthesis⁵⁻⁷ in the intestinal action of vitamin D, provide the basis of the proposal that 1,25(OH)₂-D₃ can be classed as a steroid hormone.

Fig. 1 Size of CaBP-synthesizing polysomes. 1 mg (20 A_{260} units) of polysomes from intestinal cells of vitamin D₃-dosed chicks was layered on a 15 to 45% sucrose gradient in 25 mM NaCl, 25 mM Tris-HCl, pH 7.5, 5 mM MgCl₂ and centrifuged in the SW 36 rotor for 100 min at 2° C and 35,000 r.p.m. Fractions were collected as indicated and RNA extracted and translated in the lysate as described in Table 2. ●, CaBP synthesizing polysomes; —, polysome profile.

The role of 1,25(OH)₂-D₃ as a steroid hormone implies that it acts at the level of gene transcription. We have tested this hypothesis by investigating the synthesis of calcium binding protein (CaBP), formed in response to vitamin D⁸. More specifically, we have sought to determine whether CaBP is synthesized *de novo* or formed from an inactive precursor as proposed by Drescher and DeLuca⁹ and whether the action of 1,25(OH)₂-D₃ on the nucleus promotes the formation of a specific mRNA for CaBP.

Table 1 Effect of Vitamin D on the Synthesis of CaBP by Isolated Polysomes

Source of polysomes	TCA insoluble d.p.m. in released protein	Radioactivity in immunoprecipitate (d.p.m.)
Rat liver	56,000	330
Chick intestinal mucosa (-D)	51,200	270
Chick intestinal mucosa (+D)*	64,000	4,475

* Rachitic chicks received 5 µg vitamin D₃ 72 h before being killed.

Polysomes were isolated as described¹⁰. *In vitro* polypeptide synthesis was conducted at 37° C in a medium containing 1 mM ATP, 0.4 mM GTP, 10 mM creatine phosphate, 40 µg ml⁻¹ creatine kinase, 50 µM of each amino acid except leucine, 0.5 µCi ml⁻¹ ³H-leucine, 0.2 to 0.5 mg ml⁻¹ polysomal RNA, 0.2 ml ml⁻¹ gel-filtered rat liver cell sap, 1 mM dithiothreitol and 20 mM Tris-Cl, pH 7.5. Optimal ionic concentrations were 4 mM MgCl₂ and 100 mM KCl. After 30 min incubation, ribosomes were removed by centrifugation at 150,000g (maximum) for 4 h to produce a supernatant containing released protein. Trichloroacetic acid (TCA) precipitable radioactivity was measured as described by Mans and Novelli¹⁴. Immunoprecipitates were washed twice and dissolved in 0.2 ml NCS tissue stabiliser for scintillation counting.

Table 2 Synthesis of Immunoprecipitable Protein in a Rabbit Reticulocyte Lysate Programmed with Intestinal RNA

RNA added	Total radioactivity incorporated (c.p.m. per 10 µl)	¹⁴ C precipitated by anti-CaBP (c.p.m.)
None	14,200	149
150 µg (-D)	13,700	155
108 µg (+D)*	14,300	361
216 µg (+D)*	14,000	551

* Rachitic chicks received 5 µg vitamin D₃ orally 72 h before being killed.

Incubation conditions for the lysate were as described¹⁵ except that ATP and GTP were omitted and MgCl₂ and creatine phosphate were present at 0.5 mM and 10 mM respectively; the concentration of non-radioactive leucine was 50 µM and ¹⁴C-leucine was 2.5 µCi ml⁻¹. Incubations were carried out at 30° C for 60 min in a volume of 500 µl and contained the amounts of intestinal RNA shown above. After incubation, a 10 µl sample was taken to measure TCA insoluble radioactivity¹⁶; the remainder was made 1% with Triton-X100 and deoxycholate and 10 mM with leucine. Non-radioactive CaBP (10 µg) and excess antiserum were then added to the mixture and, after 30 min at room temperature, the immunoprecipitate was collected by centrifugation through M sucrose¹¹ and dissolved in NCS tissue solubiliser.

The first question was answered by investigating the ability of polysomes isolated from rachitic and vitamin D₃-dosed chicks to synthesize CaBP in an *in vitro*, cell-free system. Chick intestinal polysomes were isolated from a post-mitochondrial supernatant by sedimentation through a 0.5 M/2.0 M discontinuous sucrose gradient as previously described¹⁰ and incubated as shown in Table 1. After the

incubation, the ribosomes were removed by centrifugation and the incorporation of ^3H -leucine into completed polypeptide chains and into CaBP was determined. The specificity of the precipitin reaction used to quantify CaBP synthesis has already been reported¹⁰. It is clear from Table 1 that tritium is incorporated into CaBP by polysomes isolated from vitamin D₃-dosed chicks. On the other hand, polysomes both from rachitic chick intestinal cells and from rat liver cells resulted in the same low level of radioactivity in the immunoprecipitate. We interpret these results as *de novo* synthesis of CaBP.

We wished to test directly the production of a specific mRNA as a result of vitamin D administration. RNA was prepared from intestinal polysomes (for method see ref. 11) and incubated in a rabbit reticulocyte lysate¹⁵. Table 2 shows that RNA preparations from intestinal polysomes of vitamin D-dosed chicks directed the *in vitro* synthesis of a product which is precipitable by our specific antiserum. RNA from rachitic chick intestinal polysomes was devoid of this activity.

Fig. 2 Sodium dodecylsulphate-acrylamide gel electrophoresis of anti-CaBP precipitable radioactivity. RNA from the peak fraction of Fig. 1 was translated in the lysate and the immunoprecipitable radioactivity recovered as described in Table 2. The immunoprecipitate was dissolved by heating to 100°C for 4 min in a sodium dodecylsulphate-Tris-dithiothreitol solution¹⁷ and then electrophoresed on sodium dodecylsulphate-acrylamide gels. Gels were prepared as described by Laemmli¹⁸ except that the concentration of bis-acrylamide was doubled. Electrophoresis was at 5 mA per gel for 100 min. After electrophoresis, 1 mm slices were cut and incubated at 50°C for 2.5 h with 500 μl NCS tissue solubiliser and 30 μl H₂O. After cooling, they were counted in a 10 ml toluene scintillator. Also shown in the figure are the electrophoretic mobilities of, A, ovalbumin (molecular weight 43,000); B, carbonic anhydrase (molecular weight 29,000); C, myoglobin (molecular weight 17,300) on parallel gels.

It was also of interest to determine the size of the CaBP-synthesizing polysomes as well as the molecular weight of the protein produced by the lysate. Thus, intestinal polysomes were fractionated on a sucrose gradient and RNA prepared, as described above, from the fractions. This RNA was translated in the lysate and immunoprecipitable material recovered. Figure 1 displays the polysome profile and the distribution of the CaBP-synthesizing polysomes. It can be seen that CaBP is synthesized on polysomes containing between eleven and fourteen ribosomes. This finding was rather surprising as ovalbumin (387 amino acids)¹² is synthesized on polysomes of the same size¹³. Indeed, we expected to find that CaBP (206 amino acids)⁶ was synthesized on polysomes containing six to eight ribosomes. This anomaly may be explained by postulating that either elongation is rate limiting or that a larger protein is produced and then cleaved after or during synthesis to yield an active CaBP. These possibilities are at present under investigation.

Finally, an experiment was performed to characterise the protein synthesized under the direction of intestinal RNA.

When this RNA was added to the lysate and the resulting antibody precipitate analysed by electrophoresis on SDS-acrylamide gels, a single peak of radioactivity was observed (Fig. 2). Moreover, the mobility of this peak corresponded to a molecular size of 26,000 daltons and was similar to that of authentic CaBP electrophoresed on parallel gels. The absence of a peak of radioactivity with a large molecular weight argues against the precursor molecule discussed above.

We have demonstrated the *de novo* synthesis of a protein having similar molecular and antigenic properties as the intestinal CaBP. The ability to synthesize this protein resides in both polysomes and RNA of intestinal cells from vitamin D₃-dosed chicks; polysomes or RNA from rachitic chicks do not possess this ability. Thus, this study supports the concept that the active metabolite of vitamin D acts in an analogous fashion to the classical steroid hormones.

We thank Dr R. J. Jackson for the supply of reticulocyte lysate, Drs N. Carey and R. D. Palmiter for helpful discussions and Mr P. W. Wilson for assistance in the antisera preparations.

Abrogation of Lymphocyte Trapping by Ascitic Tumours

SEQUESTRATION of lymphocytes within antigen-stimulated lymphoid organs is observed regularly following injection of immunogens and adjuvants¹⁻⁵. This lymphoid "trapping" is one of the earliest events in immunization and may be necessary for the expression of an effective immune response. The

mechanism responsible for controlling the operation of the "trap" is incompletely understood but must relate to the way in which lymphocytes normally recirculate.

We have observed defective lymphocyte trapping in animals bearing ascitic tumours. This defect could be transferred to normal animals by injections of cell-free ascitic fluid from animals bearing tumours. The abrogation of trapping applied not only to the tumour but to all immunogens and adjuvants tested. These observations may have relevance to the immunosuppressed state widely recorded in animals and humans bearing advanced tumours⁶⁻⁸ and to the ineffective immune response towards the tumour itself.

The method used to demonstrate lymphocyte trapping has been described in detail elsewhere¹⁻³. The extent to which lymphocytes are sequestered within antigen-stimulated lymphoid organs is measured by determining localization of ⁵¹Cr-labelled syngeneic lymph node cells 24 h after intravenous injection into animals bearing tumours or challenged with antigen. The extent of trapping is reflected by the degree to which the lymphocytes are retained in stimulated lymphoid organs in excess of the localization in untreated controls.

Groups of Balb/c mice received either 10⁷ S37 or 5 × 10⁷ Meth/A sarcoma cells intraperitoneally or were uninjected. At four daily intervals thereafter radio-labelled syngeneic lymph node cells were injected intravenously into representatives of each group and the localization of label determined 24 h later. Animals bearing intraperitoneal tumours had considerably greater localization of labelled cells in their spleens on days 1 and 2 than controls (Table 1). The distribution of labelled cells became identical to that in the controls by day 2 in the Meth/A bearing animals and by day 3 in the S37 bearing animals. (The difference of 1 d between the groups may be related to the higher dose of Meth/A tumour cells used.) Therefore in spite of the continued presence of antigenic tumour, trapping in the spleen was evanescent.

When Balb/c mice received subcutaneous implants of either tumour, augmented localization of radio-labelled cells

occurred in the draining lymph nodes. In contrast to animals bearing ascitic tumours, trapping in this case did not decay but was continuously present for as long as 40 d following implantation. Furthermore, these animals were still able to "trap" when challenged with antigen intravenously (spleen) or subcutaneously (contralateral nodes).

The failure of splenic trapping in mice bearing ascitic tumours for more than 48 h might be explained in several ways. The rapid multiplication of tumour cells in the peritoneal cavity could induce immunological non-reactivity to tumour antigen; trapping is known not to occur in tolerant mice⁹. In this case the loss of trapping would be immunologically specific. Alternatively the presence of intraperitoneal tumour might exert some general effect on the kinetics of lymphocyte circulation. To differentiate between these possibilities animals bearing ascitic tumours were challenged with antigens known to be highly effective in eliciting trapping¹⁻³ and their responses compared with those of normal controls (Table 2). The intravenous injection of sheep erythrocytes (sheep RBC), keyhole limpet haemocyanin (KLH) or Salmonella "H" antigen caused marked sequestration of radio-labelled lymphocytes in the spleens of normal animals. Animals which bore ascitic tumours (4 d after inoculation) could not produce this response. (Although not shown in Table 2, this ability to cause failure of trapping was demonstrated with Meth/A tumour as well.) A similar discrepancy was found after subcutaneous challenge with the same battery of antigens: animals bearing ascitic tumours did not show trapping in the antigen-stimulated lymph nodes.

The latent interval between peritoneal tumour administration and trapping abrogation was indirectly related to the dose of injected tumour cells. Animals receiving an initial dose of 10⁶ tumour cells continued to trap for 5 d, whereas at a high dose of tumour (10⁷ cells) trapping ceased by day 3. Antigen challenge in these animals showed a non-specific failure of trapping by day 4 in the animals given 10⁷ tumour cells. In animals given 10⁶ tumour cells the subcutaneous challenge by antigen failed to initiate trapping by day 7 while intravenous trapping failed by day 9.

Table 1 The Effect of Injection of Intraperitoneal Tumour on Lymphocyte Trapping

	Day 1		Day 2		Day 3		Day 4	
S37 sarcoma	Control	IP tumour	Control	IP tumour	Control	IP tumour	Control	IP tumour
% Localization of labelled cells in the spleen	17.2 ± 0.9	28.1 ± 1.3	16.5 ± 0.5	22.0 ± 1.5	12.6 ± 0.1	11.8 ± 0.3	12.6 ± 0.5	8.6 ± 0.6
% Trapping		63		33				
Meth/A sarcoma								
% Localization in the spleen	17.8 ± 1.0	23.8 ± 1.6	18.5 ± 2.5	20.0 ± 2.4	15.9 ± 0.8	16.2 ± 1.2		
% Trapping*		33		12		0		

Groups of mice injected with 10⁷ S37 or 5 × 10⁷ Meth/A tumour cells on day 0. On days 1-4 control and tumour-bearing animals were injected with ⁵¹C-labelled lymphocytes and the percentage of splenic localization of these cells was determined.

* Trapping of less than 20% is not considered significant.

Table 2 The Failure of Lymphocyte Trapping in Ascitic Tumour-bearing Mice (4 d)

	No antigen		Sheep RBC		Keyhole limpet haemocyanin		Sal. H suspension	
S37 tumour	Control	Tumour bearers	Control	Tumour bearers	Control	Tumour bearers	Control	Tumour bearers
% Localization in the spleen	15.3 ± 0.7	18.6 ± 0.6	27.7 ± 1.6	19.8 ± 0.3	28.2 ± 0.4	16.5 ± 0.6	25.4 ± 0.7	16.8 ± 0.4
% Trapping			81%	0	84%	0	66%	0

Mice bearing ascitic tumour (10⁷ given intraperitoneally on day 0), and controls, were challenged with SRBC, KLH or Sal. H given intravenously 1 h before labelled lymph node cells.

Table 3 The Failure of Lymphocyte Trapping in Supernatant Treated Animals

% Localization of labelled cells	Antigenic challenge		
	No antigen	Subcutaneous sheep RBC	Intravenous sheep RBC
Left lymph nodes	2.6±0.1	2.1±0.1	
Right lymph nodes	2.7±0.2	2.1±0.1	9.1±0.9
Mesenteric lymph nodes	7.1±1.1	4.9±0.3	
Spleen	18.0±1.0	15.1±0.3	19.7±0.9
Liver	28.4±1.8	23.2±0.9	17.1±0.6

Three groups of Balb/c mice were treated with 0.5 ml ($\times 3$) of supernatant raised by injection of 10^7 Meth/A tumour cells in syngeneic hosts. Animals were then challenged with antigen, subcutaneously, on day 3 and intravenously on day 4: one group was left unchallenged. ^{51}Cr -labelled lymph node cells were injected on day 4 and their percentage localization determined on day 5.

Because failure of lymphocyte trapping occurred only in animals bearing intraperitoneal tumour and affected responses not only locally but also in peripheral sites, we considered that the effect might be mediated by some tumour cell product or host factor liberated into the ascitic fluid. To test this, ascitic fluid from tumour-bearing mice was removed and centrifuged to remove cells in suspension. The cell-free supernatant was injected in varying dosages either intravenously or subcutaneously into normal Balb/c mice which were then challenged with antigen or adjuvants known to elicit trapping in untreated controls. Animals which received ascitic fluid supernatant failed to show trapping either in the spleen after intravenous antigen challenge or in the draining lymph nodes after subcutaneous antigen challenge (Table 3). Abrogation of subcutaneous trapping was observed after as little as three daily 0.1 ml intravenous doses of supernatant or a single intravenous injection of 0.3 ml. The consistent abrogation of splenic trapping requires a somewhat higher dose of supernatant, 1 ml $\times 1$ or 0.5 ml $\times 3$. This effect lasted between 24 and 48 h after three pulses of supernatant. Animals treated with supernatant also failed to demonstrate trapping in the regional lymph nodes when challenged with subcutaneous inoculation of the same tumour.

Preliminary observations suggest that the activity present in cell-free ascitic fluid supernatant is preserved after heating or freezing. Samples heated to 56° C for 30 min, or stored at -20° C for up to 3 months, or spun at 100,000g for 3 h, were still active in ablating trapping. The activity is also known to cross allogeneic barriers, that is, supernatant raised in Balb/c mice is effective in abrogating trapping in C3H mice.

If the ability to recruit lymphocytes is important for initiation of immune responses then interference with this mechanism should produce an immunosuppressive effect. The survival of DBA skin grafts on Balb/c mice was prolonged when graft recipients were treated with ascitic supernatant. The median survival time of such grafts in mice treated with 0.3 ml amounts of supernatant for 3 d was 16 d compared with 12 d in untreated controls (unpublished).

These results establish that animals bearing ascitic sarcomas develop impaired ability to recruit lymphocytes after antigen challenge. This defect is immunologically non-specific and can be adoptively transferred to normal animals by a cell-free ascitic fluid supernatant. Such a defect would be expected to result in impaired immune responsiveness, a prediction tentatively supported by the preliminary results of allogeneic skin grafting.

The observation that ascitic fluid from animals bearing tumours may have immunosuppressive properties is not new. Depression of the response to sheep erythrocytes by the administration of tumour ascitic fluid has been reported *in vivo* by Yamazaki *et al.*¹⁰ and *in vitro* by Chan and Sinclair¹¹. Apfel *et al.*¹² found that daily aspiration of ascitic fluid had a protective effect against tumours, and Groshman

and Nowotny¹³ reported that ascitic fluid antagonized the protective effect of endotoxin on tumour growth.

Whether the alteration in lymphocyte kinetics induced by tumour ascitic fluid is directly responsible for immunosuppression remains to be established. These observations offer, however, a possible explanation for the generalized depression of immune responsiveness widely recorded in animals and man with advanced cancer and provide a method for investigating this phenomenon. Moreover, these results suggest yet another mechanism whereby some tumours may escape or render ineffective the immune surveillance and destructive defence of the host. The extent to which these speculations apply to some or all tumours remains to be elucidated.

New Histone Kinases in Nuclei of Rat Tissues

THE presence of acid-stable phosphomonoesters, principally as phosphoserine, in histones has been reported by several investigators¹⁻⁴, and histone kinases which phosphorylate serine in histones I and IV have been studied widely⁵⁻⁷. Many of the histone kinases studied are stimulated by cyclic AMP^{6,8}.

In examining nuclear extracts of Walker-256 carcinosarcoma for histone kinases we have found that such extracts supplemented with whole calf thymus histones and γ - ^{32}P -ATP yield a ratio of acid-labile to acid-stable protein phosphates from 2 to 3.5, dependent on pH. Further, we have found that histones I and IV are phosphorylated to produce acid-labile phosphates by at least two separate enzymes obtained from Walker-256 carcinosarcoma nuclear extracts and similar extracts of normal rat tissues. The new kinases are apparently independent of cyclic AMP.

The new histone kinases were assayed in an incubation volume of 0.2 ml, containing: glycine-NaOH buffer (pH 9.5), 10 μmol , or maleate buffer (pH 6.5), 10 μmol ; γ - ^{32}P -ATP, 0.03 μmol , containing about 1.5×10^6 c.p.m.; magnesium acetate, 4 μmol ; ethylene glycol bis-(β -aminoethyl ether)-N,N'-tetraacetic acid, 0.03 μmol ; and histone IV or histone I, 20 μg . The reactions were started by addition of enzyme, and incubations were carried out for 5 min at 30° C. The reactions were terminated by the addition of 88% phenol buffered with 0.01 M sodium phosphate to pH 8, and the acid-labile ^{32}P bound to protein was determined by the phenol extraction-acetone precipitation method of Boyer and Bieber⁹.

Nuclei from all tissues studied except brain and regenerated rat liver were prepared by the method of Chauveau *et al.*¹⁰ except that $MgCl_2$ was used in place of $CaCl_2$. Brain nuclei were prepared by the method of Lovtrup-Rein and McEwen¹¹, and regenerated rat liver nuclei were prepared by the method of Higgins and Anderson¹².

Crude extracts from the Walker-256 carcinosarcoma nuclei, when assayed for the formation of acid-labile histone phosphates, showed a bimodal pH profile with one peak of activity at pH 9.5 (the 'pH 9.5 kinase') and another peak of activity at pH 6.5 (the 'pH 6.5 kinase'). Nuclei from rat spleen and from regenerated rat liver had activities similar to those of Walker-256 carcinosarcoma (Fig. 1a), while nuclei obtained from rat liver and from rat brain had only the pH 6.5 activity (Fig. 1b). Kidney nuclei have an apparently unique enzyme with a pH optimum about 8.7 (Fig. 1b).

The new histone kinases are principally found in the acidic protein fraction prepared from nuclei by the method of Wang¹³ and have been further purified from this fraction by isoelectric precipitation and chromatography on carboxymethyl cellulose. The pH 6.5 kinase washes through the carboxymethyl cellulose column, while the pH 9.5 kinase is eluted by 0.2 M NaCl, 0.01 M Tris-HCl (pH 7.5).

Among the basic proteins examined, histone IV is phosphorylated most extensively, while histone IIB and protamine are slightly phosphorylated by the pH 9.5 kinase. Histone I, casein, bovine serum albumin, poly-L-lysine, and poly-L-arginine are only poorly or not at all phosphorylated (Fig. 2a). The pH 6.5 kinase most extensively phosphorylates histone I, while histone IV is phosphorylated to a lesser extent (Fig. 2b). The pH 9.5 and pH 6.5 kinases are further distinguishable from one another with respect to their kinetics of phosphate incorporation, which may be related to the behaviour of histone IV in solution at pH 9.5.

When ^3H -histone IV (isolated by the Johns method¹⁴ from Walker-256 carcinosarcoma cells grown in tissue culture in medium containing ^3H -arginine) was phosphorylated using the pH 9.5 kinase and isolated by electrophoresis on cellulose acetate¹⁵ for 15 min at 110 V, the electrophoretic mobility, as measured by the co-migration of the ^3H and the ^{32}P labels toward the anode, was altered significantly from that of unphosphorylated ^3H -histone IV. The latter migrates very slowly toward the cathode under these conditions. Analogous studies using ^3H -histone I and the pH 6.5 kinase resulted in a similar alteration in the mobility of histone I. Dephosphorylation of histone I phosphate yielded free ^{32}P -phosphate and intact histone I.

Hydrolysis in 3 M KOH of the ^{32}P -labelled histone IV result-

Fig. 1 Acid-labile histone phosphate produced as a function of pH using nuclear extracts: a: —, Walker-256 carcinosarcoma; ---, rat spleen; —, regenerated rat liver. b: —, rat brain; ---, rat liver; —, rat kidney. Buffers used were: ○, ○, or ●, phosphate (Walker-256 carcinosarcoma and rat liver) or maleate (other tissues); △, △, or ▲, Tris-HCl; □, □, or ■, glycine-NaOH.

Fig. 2 Substrate specificity of the partially purified histone kinases. a, pH 9.5 kinase; b, pH 6.5 kinase. 20 μ g of the specified protein was added to the reaction mixture for each determination and assays performed as outlined in the text.

ing from the pH 9.5 kinase and subsequent paper chromatography of the hydrolysate in *n*-propanol:ethanol: $H_2O:NH_3$ (30:30:39:1) yielded ^{32}P -3-phosphohistidine. This observation has been confirmed by coupled Pronase-trypsin digestion of the phosphorylated histone IV. Studies on the chemistry of the phosphorylated lysine-rich histone produced by the pH 6.5 kinase reaction are in progress.

Our study shows the existence of at least two previously undiscovered nuclear histone kinases which catalyse the formation of acid-labile histone phosphates. Previously, the only known histone phosphates contained acid-stable phosphomonoester linkages. The two histone kinases we have found are distinguishable from one another with respect to various criteria, including the optimum pH for activity and the type of histone phosphorylated.

It is generally believed that phosphorylation of histones results in a loosening of the interaction between histones and DNA so that transcription or replication can occur. The temporal relationship of the new histone kinases to DNA synthesis and other cell cycle events is being studied with synchronised Walker-256 carcinosarcoma cells in culture.

Elevated Erythrocyte Calcium in Sick Cell Disease

CUMULATIVE membrane damage and loss is thought to occur in the erythrocytes of individuals homozygous for haemoglobin S (refs 1-4). The culmination of this process seems to be the formation of irreversibly sickled cells (ISC), which will not resume normal biconcave disk shape, even when the haemoglobin which they contain is in the sol (oxygenated) state⁵⁻⁷. Although the processes responsible for the formation of ISC have not yet been fully elucidated, it is clear that a change in the structure or composition of the membrane has occurred, such that cellular plasticity and ability to resume normal shape upon oxygenation have been lost. Weed *et al.*⁸ report a similar loss of plasticity, a diminished ease of ingress into glass microcapillaries, when calcium is placed inside resealed membrane "ghosts" made from normal human erythrocytes. In whole red cells, diminished filterability was also found to occur concomitantly with progressive loss of ATP. ATP-depleted red cells, however, retained most of their plasticity if EDTA were added to the incubation mixture to prevent calcium accumulation⁸. These results indicate that increased calcium alone may markedly reduce red cell plasticity.

From this evidence, and the fact that sickle cells, especially in the deoxygenated, sickled state, are excessively permeable to cations such as sodium and potassium⁹⁻¹¹, we postulated that increased intra-erythrocytic calcium concentrations might occur in Hb SS disease. This accumulation of calcium within the red cell might lead to diminished filterability, and, eventually, to the formation of ISC. The results reported here support this hypothesis.

Erythrocytes from heparinized blood samples were washed four times in phosphate buffered glucose saline (pH 7.40, 10 mM dextrose) before quantitative analysis of red cell calcium concentration. This was carried out by atomic absorption spectroscopy according to the techniques reported by Weed *et al.*³ except that only one trichloroacetic acid (TCA) extract was made, one volume of thoroughly washed red cells being precipitated with five volumes of cold 10% TCA with 20,000 p.p.m. lanthanum. Quantitative recovery using this extraction technique was confirmed by counting extracts of erythrocytes which had been previously equilibrated with $^{45}\text{Ca}^{2+}$. Scanning electron microscopy and energy dispersive X-ray spectroscopy were performed on erythrocytes mounted on glass cover slips, fixed in 1% glutaraldehyde and subsequently washed in calcium-free isotonic dextrose to remove surface salt contamination. Individual ISC, defined as erythrocytes deviating markedly from biconcave disk shape, and sickle erythrocytes of normal morphology were found using scanning electron microscopy (Kent-Cambridge Stereoscan microscope). Energy dispersive X-ray spectroscopy¹² was used to analyse these individual cells for calcium. This technique involves exposing portions of individual cells to an electron source and measuring the resultant dispersed energy arising from individual elements within the cell. Because this technique does not allow absolute quantitative analysis, calcium was expressed as the ratio of calcium counts to aluminium counts. The aluminium counts were simultaneously obtained from the collector face of a beryllium-windowed 'Kevex' X-ray detector. Calcium flux studies were performed using washed packed red cells suspended to 30% by volume in Krebs-Ringer bicarbonate, containing 10 mM dextrose, 2.5 mM CaCl_2 , and 5.0 $\mu\text{Ci ml}^{-1}$ $^{45}\text{Ca}^{2+}$. After incubation with labelled calcium, the red cells were thoroughly washed at 4° C to remove all external calcium, extracted with five volumes of 6.7% TCA and the residual radioactivity was counted. In all procedures, as many white cells as possible were removed.

Quantitative analysis of erythrocyte calcium by atomic absorption spectroscopy revealed that Hb SS erythrocytes contained approximately eight times more calcium than erythrocytes from normal controls (Table 1). Furthermore,

Fig. 1 Calcium leak into oxygenated and deoxygenated normal and sickle erythrocytes expressed as % of external $^{45}\text{Ca}^{2+}$ entering the red cells during 1.5 h incubation in a shaking water bath at 37° C. Samples of washed red cells were equilibrated in a tonometer with either 95% O_2 and 5% CO_2 or 95% N_2 and 5% CO_2 . □, Individual values. Means for each group are represented by the bars. Means (±1 s.d.) are as follows: oxygenated normal RBC, 0.072 ± 0.028 ; oxygenated sickle RBC, 0.840 ± 0.572 ; deoxygenated normal RBC, 0.090 ± 0.035 ; deoxygenated sickle RBC, 3.490 ± 1.884 . Significance of differences (Student's *t* test, two tailed): between oxygenated normal and sickle RBC, $t=3.177$, $P<0.01$; between deoxygenated normal and sickle RBC, $t=4.398$, $P<0.001$; between oxygenated and deoxygenated sickle RBC, $t=3.808$, $P<0.01$.

energy dispersive X-ray spectroscopy of individual Hb SS erythrocytes showed that, within the same preparation of well-oxygenated red cells, those which were "irreversibly sickled" contained approximately twice as much calcium as red cells of normal morphology. The ratio of calcium to aluminium averaged 3.01×10^{-3} (± 0.68) in eight ISC compared to 1.52×10^{-3} (± 0.04) in five sickle red cells of normal morphology ($t=4.839$, $P<0.001$).

To determine the origin of the greatly increased calcium concentrations, the influx of $^{45}\text{Ca}^{2+}$ into Hb SS red cells was measured. When washed red cells were incubated in Krebs-Ringer bicarbonate buffer with $^{45}\text{Ca}^{2+}$, the net influx of calcium into fully oxygenated Hb SS red cells was almost ten times that into normal red cells (Fig. 1). Furthermore, when oxygenated and deoxygenated (sickled) Hb SS erythrocytes were compared, it was found that calcium flux was enhanced

Table 1 Erythrocyte Calcium Concentrations in Normal Subjects and Patients with Haemoglobin SS Disease

Subjects	n	Mean	Range
Normal	14	24.9 (±8.2)	15.5-38.9
Hb SS disease	9	188.8 (±68.8)*	111.0-302.3

Values are expressed in $\mu\text{mol Ca}^{2+} \text{ l}^{-1}$ packed red cells ± 1 s.d.
* $t=8.824$, $P<0.001$ (Student's *t* test, two tailed).

more than four-fold by the sickling of Hb SS red cells. In contrast, deoxygenation had no effect on calcium leak into normal red cells. Control studies on samples from patients with elevated (>7%) reticulocyte counts revealed normal calcium flux rates (data not shown). Most of the uptake of $^{45}\text{Ca}^{2+}$ by sickle red cells probably represents exchange of unlabelled intracellular calcium for labelled extracellular calcium but three samples of deoxygenated Hb SS red cells, incubated for 1.5 h at 37° C, were found to accumulate an average of 50 μM Ca^{2+} l^{-1} of packed cells. No net accumulation was detectable in three control samples from normal individuals. This calcium accumulation in Hb SS erythrocytes was equivalent to a 25% increase in total cellular calcium.

We have found that Hb SS erythrocytes contain approximately eight times as much calcium as do erythrocytes from normal individuals, that ISC appear to contain approximately twice as much calcium as do Hb SS cells of normal morphology and that Hb SS red cells display markedly increased permeability to calcium, which is further enhanced by deoxygenation and sickling of these erythrocytes. This evidence indicates that the leakiness of Hb SS red cells leads to an abnormal accumulation of intracellular calcium. This, perhaps combined with progressive metabolic depletion, could explain the diminished filterability of oxygenated Hb SS red cells which has been reported by several investigators¹³⁻¹⁶, and is likely to be critically involved in the shortened survival of Hb SS red cells. LaCelle *et al.*¹⁷ have proposed that increased calcium and decreased ATP concentrations cause the stiffening of the erythrocyte membrane which characterizes normal senescent red cells. Membrane stiffening, in turn, would lead to sequestration and destruction of erythrocytes in reticuloendothelial organs such as the spleen and liver. A similar, though much more rapid, series of events seems to underlie the greatly accelerated red cell destruction in haemoglobin SS disease. In addition, marked calcium accumulation may be involved in the formation of ISC *in vivo*.

We suggest, as have others⁸, that calcium alters the sol-gel characteristics of the red blood cell membrane, favouring the latter. In Hb SS erythrocytes, an excessive accumulation of membrane calcium, occurring during sickling, probably "fixes" the membrane in the sickled shape, thereby producing the ISC.

We thank Professor T. E. Hutchinson for help and advice and Elaine Berger for technical assistance. We also thank Dr Hugh Chaplin for his cooperation. Supported by NIH grants.

Erratum

In the article "Accumulation of Fossil CO₂ in the Atmosphere and the Sea" by A. W. Fairhall (*Nature*, **245**, 20; 1973), Figs 1 and 2 of the original manuscript were substituted for the corresponding figures of the revised version. As far as Fig. 2 is concerned, the differences are small, but Fig. 1 (revised) contained data which were essential to the discussion. The correct figure appears below. Also line 2 of page 22 should read, " $[n_a' - n_a]/[N_a + n_a(t)]$ ", expressed as a percentage where $t' =$ ".

Fig. 1 Production of fossil CO₂ since the 1870s: the solid circles are the estimates of Revelle and Suess¹⁰ extended to 1890 by estimates of OECD, which along with the data from the 1960s are from ref. 11. The dots are estimates of Keeling¹². The dashed line is the cumulative production to the present day based on the Revelle-Suess production curve.

The author also wishes to take this opportunity to add the following information:

Using a simple box model for the atmosphere, biosphere, mixed layer of the sea, and the deep sea, and a logistic-curve representation of future fossil CO₂ emissions, Zimen and Altenheim^{1,2} have reached substantially the same conclusions as myself. In their analysis the calcite undersaturation of the sea would be reached before the turn of the century.

BOOK REVIEWS

Plants People Ate

Palaeoethnobotany: The Prehistoric Food Plants of the Near East and Europe. By Jane M. Renfrew. Pp. xvii+248 (48 plates). (Methuen: London, May 1973.) £6.50.

DR RENFREW begins this attractively produced book with a definition of palaeoethnobotany: "the study of the remains of plants, cultivated or utilised by man in ancient times, which have survived in archaeological contexts". She is concerned primarily with the palaeoethnobotany of the Near East and Europe in prehistoric times and with plants utilised for food rather than as sources of structural materials, textiles, dyes or medicaments. Her main intention is to bring together in a single volume the information available for the identification of archaeological plant material, for without accurate identification the results of palaeoethnobotanical investigations cannot be interpreted meaningfully. The book therefore describes and assesses the evidence from which it has proved possible to attempt a reconstruction of the history of man's plant foods during the past ten thousand years or so.

The initial chapter reviews the development of palaeoethnobotanical research since the pioneering publications of C. Kunth (1826) and Oswald Heer (1866), and pays just tribute to the long series of fundamentally important contributions by Hans Helbaek, of the National Museum in Copenhagen, whose establishment of principles and techniques for the identification of plant remains and especially of seeds, grains and fruits has placed all workers in this field deeply in his debt.

There follows a general survey of the evidence, the survival of which has been for the most part due to carbonisation by heat, continuous waterlogging in peat deposits or desiccation in desert sand but also to the accidental preservation of impressions of seeds and fruits in the wet clay of pottery before firing or, less frequently, in the mudbrick or daub of walls before sun-drying. With regard to the very large numbers of grains and seeds found carbonised, Dr Renfrew gives no support to the belief that this might be the result of spontaneous anaerobic processes taking place at normal temperatures but regards carbonisation as arising simply from overheating near a hearth or in a parching oven or sometimes from a house fire: she reminds us that the ears of hulled wheats require parching before they can be successfully threshed or winnowed. She, like many others, has

been concerned about the effect of carbonisation, or indeed of any mode of preservation, on the dimensions and shape of plant parts and she quotes the results of experiments, including her own, which enable estimates to be made of the extent of deformation in various circumstances. It is of interest that prehistoric grains must in most instances have been smaller than their counterparts of today.

Carbonised material may preserve a good deal more than the gross morphological features: "occasionally the surface . . . is so well preserved that it is possible to study the cell pattern and even the structure of the hairs". Helbaek has shown, too, that silica skeletons of epidermal cells of cereal grains and their glumes may persist even in impressions in mudbrick or baked clay, thus much increasing the possibilities of critical identification. It seems likely that the services of the scanning electron microscope will become increasingly valuable in future.

The palaeoethnobotanist seeks to answer such questions as what type of food economy was practised and, if there was crop agriculture, what were the crops, whether they were grown singly or in mixture and in what relative amounts. This demands not only the discovery of suitable sites but also the correct decisions as to how the plant remains are to be extracted and sampled. Dr Renfrew shows in a table of results from Tell Azmak in Bulgaria that the whole of the material in a single find may constitute too small a sample for any but very hazardous inferences: finds at contemporary levels in the same site have remains of from one to five plant species. Even where there is adequate material there are dangers of sampling bias from various causes, and the finds themselves are likely to be products of some degree of contemporary selection, so that interpretation must be doubly cautious. The whole topic is of the utmost importance and it could be argued that Dr Renfrew might have devoted even more space to it.

Chapters 4 to 16 describe the major temperate food plants of prehistoric sites, indicating the location and dating of their finds and explaining how they can be identified and differentiated from their closest relatives. There are many excellent line drawings by Alan Eade and some informative half-tone plates at the back of the book. There are also numerous tables of characters and measurements, so that palaeoethnobotanists should be greatly assisted in solving problems of identification.

Chapter 20 considers the food values of prehistoric plant foods, but it is difficult to infer more than that the foods included important sources of carbohydrates, fats and proteins and that various fruits were probably eaten fresh: green foods would not have been preserved. The final chapter is a brief review of the origins and development of crop agriculture in the Near East and its spread to Europe. Dr Renfrew's own investigations in Europe give great weight to her views on this topic. She accepts that the first farmers reached the Balkan Peninsula soon after 6000 bc and that they brought emmer wheat as the chief cereal crop, together with einkorn wheat, both two-row and six-row barleys, oats and various pulses. The naked club and bread wheats appear quite early in the neolithic, but spelt wheat and rye not before the late neolithic. Dr Renfrew is rightly content to present the archaeological facts and does not much concern herself with evolutionary theories based on cytogenetic findings. A much larger body of archaeological data seems necessary before workers should be worried by any failures of the two lines of approach to yield identical conclusions.

Dr Renfrew emphasises the antiquity and scale of the cultivation of leguminous crops. Peas, lentils and vetches found in the earliest farming sites may have been collected in part from wild plants, but the cultivation of pulses seems as old as that of cereals. Much of the general interest of this book lies in the information provided about food plants other than cereals and pulses. Thus acorns, pistachio nuts, cornelian cherries (*Cornus mas*) and crab apples occur in early neolithic farming sites in SE Europe, and figs, wild pears and wild grapes in Greece from the late neolithic onwards. Further north there is evidence for the collection or cultivation of cherries, bullaces, sloes, raspberries, blackberries, haws, whitebeam fruits, rose hips, elderberries, bilberries and water chestnuts (*Trapa natans*). Besides acorns there are almonds, walnuts, hazelnuts and beech-nuts; and there are the numerous weed seeds which are known to have been collected, some more and some less intentionally, and eaten in bread or porridge. The whole list is interesting and impressive as illustrating the large-scale persistence of food collecting into the agricultural period.

There are a few misprints and a few obscurities, and Helbaek's 1963 publication, cited on pages 9 and 11, does not appear in the bibliography. These are small matters. Dr Renfrew must be

congratulated on having achieved her aim of providing for palaeoethnobotanists a much more comprehensive and systematic guide to the identification of plant remains than has been available until now and, moreover, of providing at the same time a very welcome source book of information for the general scientific reader.

A. R. CLAPHAM

The Excitable Heart

Electrical Phenomena in the Heart. Edited by Walmar C. De Mello. Pp. xv+415. (Academic: New York and London, October 1972.) \$26.

New blood has kept the field of cardiac electrophysiology fertile and by drawing upon it Professor De Mello has ensured the success of his enterprise, although the absence of a preface is a pity. Those starting a career in cellular physiology and biophysics, and to whom the book is addressed, need to know how the editor views the subject as a whole: better to expose the logic or hunch by which the chapters have been strung together than to imply questionable connexions by tacit juxtaposition.

The volume opens with "Electrical Properties of Embryonic Heart Cells" by N. Sperelakis. From the biological point of view this is a rational beginning, but since familiarity with the electrophysiology of the adult tissue is required for the appreciation of this informative article, some readers will find W. K. Berger's chapter on "Ultrastructure and Function of Cellular Contacts" an easier starting point. The morphology of cardiac muscle and the mechanism of excitation spread are well reviewed therein. H. Fozzard's lucid article on membrane capacity of cardiac muscle cells, out of place as chapter 8, might well be read next since structural considerations enter closely into the interpretation of the measurements.

The task of exposing the nature of the cardiac action potential is shared out between J. Dudel who deals mainly with the fast excitation process, and D. Noble and R. W. Tsien who cover the events during the plateau phase in a helpfully interpretative way. The generation of action potentials in spontaneously beating Purkinje and auricle fibres is touched upon briefly by both Dudel and Noble and Tsien. The reader pursuing the leads to voltage-clamp experiments given in their articles will find that the pacemaker potential can also be ascribed to voltage and time-dependent conductance changes controlling the downhill flow of ions. Quite a different hypothesis is advanced by T. C. West who, in writing on "The Electrophysiology of the Sinoatrial Node", holds the main brief to deal with cardiac autorhythmicity. On the basis

mainly of the high temperature coefficient of the heart rate, he implicates active inward transport of potassium ions in the fall of K permeability during the diastolic interval. As an alternative hypothesis this may well require consideration, but it is puzzling why the voltage-clamp experiments bearing on the problem of autorhythmicity have been totally ignored. Presumably the editor was left to turn diverse views to constructive ends; but in the event this task falls upon the reader. From the touchlines the editor does, however, bias the issue by setting H. G. Haas's article on "Active Ion Transport" immediately before that on the sinoatrial node, as if the consideration of active transport were an essential preliminary to the problem of autorhythmicity.

Taken by itself the chapter on active transport makes rewarding reading. The emphasis placed on the great sensitivity of the cardiac action potential to variations in the metabolic state of the cells is well placed as this remains a pressing problem. The case for the participation of metabolically driven currents in shaping the action potential is, however, not compelling. A less direct mechanism, say a change in the intracellular concentration of an ion determining a surface potential on the inner face of the excitable membrane, could equally well be at work.

Under the title "Cardiac Innervation and Synaptic Transmission" M. Anderson and J. del Castillo cover the recent revival of histological research into the rich innervation of the specialized regions of the heart. The high chemosensitivity of natural pacemaker fibres permitted some time ago the demonstration of the mode of action of acetylcholine. The more recent work on the inotropic action of adrenaline is well summarized, but the treatment of the chronotropic action suffers from the inadequate cover given earlier in the book to the known kinetics of the pacemaker current.

From a perceptive chapter on atrioventricular transmission by C. Mendez and G. R. Moe it becomes clear that the slow inward current system plays an important part in the propagation of excitation through the node. At this point one misses in this otherwise laudable multinational book a contribution from one of the French laboratories where the slow inward current system has been explored.

After interesting chapters on "Comparative Aspects of Electrogenesis" by F. V. McCann and on "The Healing-Over Process" by W. C. De Mello the volume is rounded off with a comprehensive article on "Calcium Movements and Excitation-Contraction Coupling" by J. B. Bassingthwaite and H. Reuter.

O. F. HUTTER

Feeding Children

Malnutrition and Retarded Human Development. By S. L. Manocha. Pp. xv+382. (Charles C. Thomas: Springfield, Illinois, September 1972.) \$19.75.

We have known since the early years of this century that good nutrition has something to do with physical and mental development, and in many countries practical schemes to feed growing children as well as possible have been introduced. During the past twenty years or so during which international concern over the world food situation has intensified there has been increasing effort to solve questions relating to the nutritional needs of children, with the general aim that children everywhere shall be adequately nourished.

Many scientific problems remain to be solved, but much is now known about the nutritional needs of children and how to meet them, and Dr Manocha has done a useful service in assembling so much material in this review. His book, which is intended for the educated layman as well as the professional reader, is clearly and simply written. He discusses the biochemistry and physiology of human development, particularly of the brain, environmental influences, including socio-economic factors, maternal nutrition and food habits, and such practical matters as government schemes to alleviate malnutrition, guidance on the direction and treatment of the diseases of protein-energy malnutrition, and nutrition education.

Dr Manocha writes from an international point of view and shows by the number and variety of the references he cites that he has crossed national boundaries and brought together relevant material from established and active workers in all continents. Each of the nine chapters of the work ends with a list of authoritative references ranging in time from the early years of international anxiety about malnutrition in children to 1971. These lists would by themselves be invaluable to any student of nutrition.

One could point to minor errors in the names of certain authors and to the omission of ideas that appear to be becoming of crucial importance, such as how the overriding socio-economic problems of modern society are to be solved if proper physical and mental development is ever to be achieved for all human beings. But to do this would be to carp. This book can be recommended as a useful, comprehensive, simply written review of an important and topical subject. It could be read with profit by anyone who wishes to understand more about one of the most intractable subjects of our age.

D. F. HOLLINGSWORTH

Brown on Boranes

Boranes in Organic Chemistry. By Herbert C. Brown. Pp. xiv+462. (Cornell University: New York, August 1972.) \$24.50.

THIS book is part of a distinguished series in which eminent chemists have provided written records of their Baker Lectures at Cornell University. Professor Brown essentially gives a scientific autobiography. In this sense the title of the book is misleading in that the subject of organoboranes forms but one of six parts discussing various aspects of borane chemistry.

In part 1 the principal topics relate to diborane and borohydrides, and free radical substitution reactions. These two diverse topics commanded Professor Brown's interest because of the presence at the University of Chicago of H. I. Schlesinger and M. S. Karasch.

Part 2 is devoted to Brown's contribution to the assessment of the role of steric strains in chemistry. His work on donor-acceptor addition complexes of boron led him to the idea of these as models for saturated carbon compounds—strained homomorphs and the classification of steric strains (F-, B-, I-strains).

The non-classical ion problem, which is the topic of part 3, has been the subject of long-standing controversy, particularly with the late Saul Winstein, and has now become a part of chemical folklore. The relationship to the boron studies is perhaps based on the tenuous recognition that a carbonium ion is iso-electronic with a borane.

Part 4 is concerned with selective reductions using hydrides or complex hydrides of boron and aluminium and the question of selectivity. Reagents such as disiamylborane are uniquely associated with Brown, not least in their nomenclature.

In part 5, which is devoted to hydroboration and essentially updates Brown's monograph on the subject of 1962, the author is mainly concerned with boron-carbon bond-making. The term "hydroboration" is probably interpreted by the organic chemist as a combination of this process together with a subsequent boron-carbon bond-making, usually without isolation of the boron intermediate. The value of the overall procedure lies in a combination of factors which includes mild reaction conditions, essentially quantitative yields, a high degree of selectivity and stereospecificity, and a multiplicity of similar specific cleavage reactions. Thus it is possible to convert acetylenes or olefins to numerous functional derivatives including higher homologues. Part 6 deals with organoboranes from the point of view of boron-carbon cleavage reactions. From the standpoint of the

organic chemist, parts 5 and 6 thus form a continuous story.

Professor Brown is, and has been, one of the giants of chemistry of the last thirty years. He is a splendid controversialist, both verbally and in writing, and the present contribution is in this same happy tradition. M. F. LAPPERT

Structures in Cells

The Generation of Subcellular Structures. By R. Markham, J. B. Bancroft, D. R. Davies, D. A. Hopwood and R. W. Horne. Pp. x+372. (North-Holland: Amsterdam and London; Elsevier: New York, 1973.) Dfl 45; £7.

THE three-dimensional structures of subcellular biological systems and mechanisms for their biosynthesis are now elements of perhaps the most important next stage in molecular biology. The problem is ripe for attack and the timing and choice of this subject for the first John Innes Symposium (held in July 1972) could not have been more appropriate. It has been excellently organized and the individual subsections well selected, being here presented in a series of stimulating articles by leading exponents from many parts of the world.

Prefaced by a suitably general historical review of molecular genetics in the form of the sixth Bateson Memorial Lectures by W. Hayes, the proceedings of the meeting include a fairly wide collection of original reports on the structure and synthesis of organelles (usually in the form of summaries of recent advances). The range stretches from relatively simple systems such as bacterial flagella and plant viruses through larger viruses, such as T₄ phage, towards bacterial spores and the more complex sophistications of ribosomes, cell walls and mitochondria. Contributors include D. Kerridge, H. R. Revel, E. Kellenberger, J. G. Atabekov, M. Nomura, R. A. Cox, A. Ryter, P. C. Fitzjames, Audrey Glauert, B. A. Afzelius and many others.

It is worth noting that all the systems considered here derive from viruses or prokaryotes, where the relatively simple structures involved are easier to study than the complexities of eukaryotes, but where the basic lessons to be learnt and the models that emerge are applicable to all types of living systems.

Perhaps the most fundamental problem in this field is the extent to which all necessary information for the correct assembly of subcellular organelles (indeed for the whole cell, for that matter) is contained in the structures of their constituent molecules. Another (slightly more restricted) way of putting it would be to ask whether the DNA or RNA genome contains all the necessary instructions for putting together the nor-

mal three-dimensional structures involved. This naturally leads to two rather more specific queries. (1) How far can assembly of multimolecular complexes occur in the absence of pre-existing structure and, in cases where some sort of pre-existing structure is required, how specific must it be? (2) To what extent, in the construction of such complexes, is a sort of scaffolding necessary—in the sense of an essential structure that is not contained in the final finished organelle?

The articles in this symposium do not of course provide a complete, generalized answer to this sort of question. But they begin to indicate the sorts of ways in which answers can be given. It would be impossible to summarize any general conclusions, although the reader is left with a strong feeling that this is an area where much progress will occur rapidly during the next 10 years.

Perhaps, above all, what has emerged fairly clearly is the extent to which spontaneous assembly of relatively complex structures can occur (being often demonstrable *in vitro*) simply through molecules "finding each other" by interactions between complementary patterns on their surfaces. Temporary scaffolding, specific catalysis by enzymes, complex "foundation" molecules acting as a specific nidus for the association of other key molecules—if they exist (as they appear to do in certain cases)—are not always necessary, although there is often an obligatory sequence in the assembly process (for example, with ribosomes) and/or a polarity in the direction of build-up, even of monomers in simple complexes such as flagellar filaments.

Having emphasized what a fascinating collection of articles is here available in an exciting field, some protest must be made about the publication itself. The offset-type process used is more tiring and difficult to read than ordinary print, the legends are not properly distinguished from the text, some tables are in type almost too small to decipher, the section headings do not stand out clearly and italics are not properly visible. The discomfort involved might be tolerable if the book were cheap.

M. R. POLLOCK

Practical Concern

Guide for Safety in the Chemical Laboratory. Second edition. (Manufacturing Chemists Association.) Pp. vi+505. (Van Nostrand Reinhold: New York and London, 1972.) £8.75.

A SMALL stretch of the imagination should inform us that the first task of the contemporary, socially concerned scientist is to make sure that neither he nor those working with him are blown up, burnt to cinders or dissolved in acid. Yet it is a matter of record

that very few institutions of higher learning are giving their students anything but the most cursory advice in laboratory safety and accident prevention on the time honoured basis that God, somehow, will couple the shorn lamb with the careless chemist. Industry, whose managers tend to be better informed on the hard realities of economic loss and the trade unions' inclination to fight compensation suits, is understandably more advanced.

In this situation it is always pleasant to welcome a new book which advocates more thought in the design and manning procedures of laboratories. Such publications come in two types: one, for example the *Handbook of Laboratory Hazards*, now published by The Chemical Society, lays emphasis on what to do once the accident has occurred and notes those chemicals with which potential danger is always present. The volume under review, produced by the American Manufacturing Chemists Association, takes a step back and considers safety as a logical outcome of sensible design and behaviour. Except in the most general sense it is not suitable as a quick reference volume in moments of stress: although it abounds in tables, so it does in cross references which take some time to follow through. But as background reading it is most valuable, for it takes nothing for granted and leads the teacher or laboratory supervisor step by well illustrated step through all the pitfalls of space, instruments and chemicals—when did you last test your fire extinguishers?

Frequently American practice differs from the British and there are variations in detail in regulations and materials standards: hence reference to ASTM. Nevertheless those whose work involves the manipulation of chemicals and the safety of the people concerned will derive great benefit from keeping *Guide for Safety* on their bookshelves, especially in the unlikely event that a fit of generosity from UGC, DES or head office allows them to translate dreams of a new laboratory into reality.

PETER FARAGO

Particle Physics

Elementary Processes at High Energy. ("Ettore Majorana" International Centre for Scientific Culture, 1970 International School of Subnuclear Physics, a NATO-MRI-MRST Advanced Study Institute sponsored by the Regional Sicilian Government and the Weizmann Institute of Science, Erice, July 1-19.) Edited by A. Zichichi. Part A. Pp. xix+1-448. Part B. Pp. xvii+449-861. (Academic: New York and London, April 1972.) \$29.50 each part.

THIS two-volume record of the 1970 International School of Subnuclear

Physics held at the hill-top town of Erice in Sicily, is a welcome addition to the scientific literature on elementary particle physics. It maintains a very high standard, and contains many lectures and discussions with permanent value.

Volume A contains the lecture courses and the review lectures, the relevant discussions being collected to follow each set. The lecture courses were of course quite topical. The opening lecture, "Electron-positron annihilation", by N. Cabibbo, was especially timely, in view of the recent operation of the electron-positron storage ring ADONE at Frascati and the early experimental results reported at the School by Italian groups working with ADONE.

G. Veneziano contributed an outstanding set of lectures about narrow resonance models compatible with duality. Besides his illuminating discussion of the origination of the model, he described clearly its generalisation to the N-point functions which many authors have discussed for scalar particles in the literature. T. D. Lee lectured on the Lee-Wick formulation of quantum electrodynamics, which makes use of an indefinite metric; his lectures included a critical analysis of the notion of causality, as used in elementary particle physics. H. Harari presented the qualitatively successful picture of hadron reaction processes which has resulted from an amalgamation of the duality model, the absorption model, and the quark model. Here his lectures are compressed into a novel but effective format, a picture book approach consisting of twenty-nine figures, self-explanatory to some extent but each with a figure caption, and a number of remarks added by way of introduction and conclusion. Whereas Harari's "picture book" occupies twenty-two pages, the discussion following them goes on for a further thirty-four pages.

Two review lectures on gravitational topics were given by W. Thirring from an elementary particle physicist's viewpoint, "more than a sort of exercise in Riemann geometry for esoteric theoreticians; something more down to earth". His second lecture "A trip behind the Schwarzschild radius", would, perhaps, be entitled today "Inside a black hole". Once considered outside elementary particle physics, gravitational topics are now attracting and intriguing many people in this field. Two review lectures were also contributed by T. D. Lee, the first an interesting introduction to symmetry principles in physics, and the second a critical discussion of published derivations of the $\Delta I = 1/2$ rule from soft pion theorems. Coming from Frascati, G. Salvini surveyed the status of experiments on electron-positron storage rings which bear on quantum electrodynamics, on the vector dominance model for photon interactions and on searches for new vector mesons. Finally, B. Maglic reviewed the problems of meson spectroscopy, including his proposal to study $\pi-\pi$ and $\mu-\mu$ collisions at low energy, using the self-colliding orbits of his "Preceptron" device.

The seminar talks are collected together in volume B, and cover a wide range of topics, not all of which can be mentioned here. J. Adams recounted the possibilities considered for the super-CERN accelerator. His words are interesting to read today, and make us realise how wise was the final decision, in relation to the boundary conditions which existed at that time. V. Weisskopf contributed an instructive seminar about nucleon structure, as seen in the light of the scaling law now established for inelastic scattering. The study of $\pi\pi$, $K\pi$, and $K\bar{K}$ interactions was covered thoroughly in an extensive series of seminars by P. Schlein. Especially appropriate at this School were the seminars contributed by M. Conversi and by A. Zichichi, concerning the work in progress by their groups at ADONE.

Many other seminars with much topical interest were also given, about the light-cone behaviour in quantum field theory, and its application to lepton-pair production, about vector meson dominance and deep inelastic electron-proton scattering, about the Pomeranchuk theorem and the possible ways in which it may fail, about SU(4) symmetry and its merits with respect to weak and strong interactions, and about PCAC, among other topics. One topic unusual for such a school was that discussed by U. Amaldi, the developments in nuclear physics which have been achieved by using high-energy particles produced by energetic accelerators. He described particularly how the analysis of quasi-free collisions, processes of the type (p,2p), has provided our strongest evidence for the validity of shell-model wave functions for light nuclei. The closing lecture, an interesting and authoritative history of the development of our knowledge of the properties of the weak decay interactions, was given by T. D. Lee.

The extensive discussion after each lecture has been an outstanding feature of the Erice School, and this has been recorded in full in these volumes. The audience included many students at the postdoctoral level, as well as many senior visitors who were there to lecture or to give seminars. Consequently, this discussion was at quite a high level, and frequently very illuminating. The record of these discussions is one of the most valuable aspects of this book.

R. H. DALITZ

CORRESPONDENCE

CO₂ Pollution of the Sea

SIR,—A recent communication (*Nature*, 245, 20; 1973) suggested that a slight increase in partial pressure of CO₂ would shift the HCO₃ equilibrium system far enough to prevent secretion of shells in marine corals and molluscs.

The lower carboniferous shells were secreted when the partial pressure of CO₂ was more than 300 times current levels (before the carbon of the coal measures was produced by species which themselves required high partial pressures of CO₂ to grow so luxuriantly).

The two statements are incompatible although the chemistry seems equally valid in both cases. However, I have never seen a systematic approach to palaeoatmospheric analysis and have long wondered at the ability of species to proliferate in spite of using an oxygen combustion system, in an atmosphere rich in CO₂, with primitive respiratory systems and inefficient internal oxygen transport arrangements. Popular assumptions about the primitive atmosphere may be wrong, otherwise ethologists have problems they have neglected.

Yours faithfully,

G. A. WOOD

13 Clifton Park Road,
Davenport Park,
Stockport

Are Conferences Necessary?

SIR,—As a means of communication of scientific data and theory, are conferences worth the money and effort being spent on them? Many think not, but

before such established and prestigious activity can be changed it is scientifically proper that experiments should be done.

Recently an attempt was made to break the established pattern by having a meeting based on the following concepts: (1) that satisfactory communication can only be achieved if the participants are limited to those actively engaged in relevant experimental work and who can sit around one, albeit large conference table; (2) that this close interaction between participants be maintained away from the conference table; (3) that participants should arrive knowing in detail the topics to be discussed; (4) that experiments to resolve some of the controversial problems described in the papers should be made at the meeting; (5) that these experimental procedures should be able to be changed on-line at the suggestion of the participants.

The subject of the conference was "Event Related Slow Potentials of the Brain" and was concerned with the changes of the electroencephalogram associated with external stimuli and with voluntary and involuntary motor movements ranging from speech to spinal reflexes. Forty-five invitations were sent to active workers in the field. It was estimated that about 200 people would have attended an unrestricted conference. The meeting was held in a relatively inaccessible college in which most of the participants were accommodated. Most of the forty papers were precirculated and only discussion was allowed at the meeting. One and a half days were devoted to experiments performed in the research laboratory of this Institute and relayed by closed circuit television.

There was no mixing or editing of pictures from the four cameras as in normal television procedure; all cameras were on all the time and thus gave considerably more information than if the audience were in the laboratory. A television camera and microphone in the auditorium permitted participants to communicate with the demonstrators.

The demonstrations were separated into five sessions representing five aspects of the congress theme. They were presented by selected groups of participants with the help of the Institute staff. A total of 12 h television transmission was achieved.

There was good interaction between experimenters and audience and on occasions the experiments were modified to clear a particular point in dispute. These were experiments in the true sense of the word—procedures adopted on chance of their succeeding. All participants were enthusiastic about these experiments.

This format for conferences appears to be of considerable value in the presentation of data and organisers of meetings are urged to reconsider their objectives and methods and to carry out the necessary experiments.

Yours faithfully,

R. COOPER

Obituary

A. G. Sharov

THE prominent insect palaeontologist Dr Alexander Grigorievitch Sharov died suddenly in Moscow on July 10, 1973.

Dr Sharov was born in 1922 in the village of Lukino, Moscow Region. While still a schoolboy he developed an interest in entomology, collecting insects and observing their habits and behaviour. After finishing school in 1939, he entered the Biological Faculty of Moscow University and specialised in entomology. While an undergraduate he took part in expeditions to the Far

East, Transcaucasia and Central Asia, where he collected material and made many interesting observations on the local faunas.

In 1943 Sharov was enlisted in the army and his military service lasted until the end of the war. He returned to Moscow University in 1945 and completed work for his diploma. In his student days, as in his later scientific work, Sharov was interested in the problems of insect ontogeny and evolution. His postgraduate studies began in the Institute of Evolutionary Morphology in Moscow, under the guidance of such prominent scientists as Pro-

fessors D. M. Phedotov and M. S. Ghilarov. In 1950 he was awarded a doctorate for his thesis on the 'proto-metabolous' development of the Thysanura and its bearing on insect phylogeny.

During the next few years Sharov's interests turned to fossil insects, and in 1955 he moved to the Palaeontological Institute of the Academy of Sciences of the USSR. There he worked until his death on the palaeontology, phylogeny and evolution of insects. He took part in many expeditions, collecting much remarkable fossil insect material. One of his most important discoveries was

that of the new order Monura, which he considered to be primitive ectotrophic Apterygota.

Sharov's works on the fossil insects of the Kuznetsky Basin are well known and highly regarded by insect palaeontologists. Most of his new discoveries were of Orthopteroid insects, and in 1968 he published a monograph on the phylogeny of this group. This comprehensive study, which was published in an English edition in 1971, will no doubt be the standard work on this subject for many years to come.

Sharov published a total of sixty-four papers and books. As well as a first-class scientist, he was a friendly and charming person, and his loss will be felt deeply by his many friends and colleagues.

Announcements

University News

Professor D. Samuel, Professor of Physical Chemistry, Weitzman Institute, has been appointed a Visiting Professor in the Department of Zoology and Comparative Anatomy, University College London.

Appointments

Dr J. W. B. King has been appointed director of the **Agricultural Research Council's Animal Breeding Research Organisation**.

Mr R. E. Boote has been appointed director of the **Nature Conservancy Council**.

The full membership of the **Computer Board for Universities and Research Councils** is now **Professor D. J. Finney**,

Professor A. J. Brown, **Mr A. H. Duncan**, **Professor J. C. Gunn**, **Dr J. Howlett**, **Professor K. W. Morton**, **Professor H. H. Rosenbrock** and **Professor M. Wells**.

Miscellaneous

Dr Basil Bard, Managing Director of the **National Research Development Corporation**, has been awarded the **Gold Medal** of the **Licensing Executives Society**.

Erratum

In the article "Comparison between Ice Age and Present General Circulations" by **E. B. Kraus** (*Nature*, **245**, 129; 1973), equation 1 should read $\theta_c = \theta_{exp}(rL/c_p T)$, and Table 1, line 4, should read $T_3(^{\circ}\text{C})$. Ref. 9 should also be changed to read **Bonatti, E., and Gardner, S.**, *Nature*, **244**, 563 (1973).

Corrigendum

In the article "Prostaglandin Production and Bone Resorption by Dental Cysts" by **M. Harris**, **M. V. Jenkins**, **A. Bennett** and **M. R. Wills** (*Nature*, **245**, 213; 1973), PGF_1 , PGF_2 and PGF_3 should read PGF_{1a} , PGF_{2a} , and PGF_{3a} throughout.

International Meetings

November 21, Symposium on Acylation (The Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London, SW1X 5AG).

December 5-6, Food Hygiene and the European Economic Community (Mr M. D. Ranken, BFMIRA, Leatherhead, Surrey).

December 6, Feeding the Newborn: Comparative Problems in Animals and

Man (Dr J. D. Sutton, National Institute in Dairying, Shinfield, Reading RG2 9AT).

December 6-7, Physical Properties of Solids at High Pressure (The Meetings Officer, The Institute of Physics, 47 Belgrave Square SW1X 8QX).

December 11, The Penetration of Liquids into Solids (The Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London SW1X 8PS).

December 11, Teaching of Physics in Electronics Courses (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1X 8QX).

December 14, Glaucoma Symposium (Office of the Director, The University of Texas Health Science Center at Houston, Division of Continuing Education, PO Box 20367, Houston, Texas 77025).

December 17-19, Computers in Spectroscopy (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1X 8QX).

December 17-21, Congress on Marine Waste Disposal (Professor E. F. Frangipane, Institute of Sanitary Engineering, Milan Polytechnic, Piazza Leonardo de Vinci 32, 20133, Milan, Italy).

December 18, Recent Developments in Antibiotics (Dr J. F. Cavalla, John Wyeth and Brother Ltd, Huntercombe Lane South, Taplow, Maidenhead, Berks).

December 18-19, Polysaccharides: their Physical Chemistry and Molecular Biology (Dr D. A. Rees, Unilever Research, Port Sunlight, Cheshire).

December 26-31, American Association for the Advancement of Science Annual General Meeting (AAAS, 1515 Massachusetts Avenue, NW, Washington DC 20005).

Maritime Studies and Management

Editor: Professor A. D. Couper, *University of Wales Institute of Science and Technology*.

Assistant Editors: C. H. Cotter, P. H. Fricke, W. E. Scobie, *University of Wales Institute of Science and Technology*.

There is an increasing amount of maritime research being undertaken by economists, geographers, lawyers, social scientists and maritime studies specialists within universities and colleges, and by managers and planners in industry, government and international agencies. Many of the results are inaccessible other than through specialist publications relating to particular disciplines. This new journal will bring together papers concerned with the maritime world which will be of interest and value to teachers, research workers and managers.

Frequency: Quarterly.

Subscription:

Libraries £8.00 per annum.

Additional: £6.00 per annum.

Private: £6.00 per annum.

SCIENTIFICA (PUBLISHERS) LTD.
42-44 Triangle West,
Bristol, England BS8 1EX.

Chance, Coincidence, Telepathy?*

**Alister Hardy,
Robert Harvie and
Arthur Koestler**
**THE CHALLENGE
OF CHANCE**

A fascinating,
speculative book
extending the frontiers
of our understanding
of coincidence and
precognition.

£3.00

*Some of the remarkable results obtained in a series of experiments into telepathy conducted by Professor Sir Alister Hardy and psychologist Robert Harvie in 1967, involving two hundred people. The 'target' was selected at random by one group, and then matched by another who chose a 'response' drawing.

Hutchinson

Biologic differentiation -a new journal.

Biological research has for too long suffered from restricted experimental attitudes and 'vertical' thinking.

Now Differentiation, an important new publication, provides the opportunity for interdisciplinary communication and increasing fertilization of ideas across the artificial boundaries created by overspecialization. This journal, published bi-monthly, offers up to date information and synthetic views of a problem underlining the whole biological phenomenon - differentiation.

The first three issues contained papers on:
Degree of differentiation in nonproliferating cells of mammary carcinoma. C. V. Wylie, P. K. Nakane and G. B. Pierce.

Polyribosome profiles and polyribosome-associated RNA of Friend leukaemia cells following DMSO-induced differentiation. H. D. Preisler, W. Scher and Charlotte Friend.

Studies on cytology and differentiation in Sciaridae. 5. Electron microscopic studies on the salivary glands of *Bradysia elegans* Morgante (Diptera, Sciaridae). A. B. Da Cunha, R. W. Reiss, C. Pavan, J. J. Bieseke, J. S. Morgante and M. C. Garrido.

The principle of sequential dependence in cellular differentiation. P. A. Riley.

The next issues of Differentiation will contain:

Time lapse filming of cellular interactions in organ culture. 2. The behaviour of malignant cells. E. J. Ambrose and Dorothy M. Easty.

Intercellular levels of cyclic nucleotides during cell enlargement and cell division in excised tobacco pith tissues. C. V. Lundeen, H. N. Wood and A. C. Braun.

Pattern formation in *Dictyostelium discoideum*: temporal and spatial distribution of prespore vacuoles. Ursula Muller and R. Hohl.

The enrichment of egg-type RNA in cleavage stage embryos of the sand dollar *Dendraster excentricus*. Shigeki Mizuno, H. R. Whiteley and A. H. Whiteley.

DNA synthesis and the production of antibodies by lymphoid tissues. G. Harris.
Neurite extension by mouse neuroblast: evidence for two modes of induction. P. Furmanski.

The journal aims to cover the following areas of study: embryonic Differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions *in vivo* and *in vitro*, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Contributions for publication are invited by The Editor.

Editor: Dimitri Viza. Faculté de Médecine Pitié-Salpêtrière, Pathologie Générale et Expérimentale, 105 Boulevard de l'Hôpital, 75634 Paris Cédex 13, France.

Editorial Board: E. J. Ambrose, R. Auerbach, J. Brachet, A. Braun, D. A. L. Davies, B. Ephrussi, H. Holtzer, F. Jacob, N. J. Jerne, C. Kafani, G. Klein, Rita Levi-Montalcini, A. Lwoff, R. G. McKinnell, C. L. Markert, Beatrice Mintz, C. Pavan, B. Pierce, S. Spiegelman, G. Tocchini-Valentini, S. Toivonen, D. Yaffe, T. Yamada.

Cited in Current Contents.

APPOINTMENTS VACANT

THAMES POLYTECHNIC SCHOOL OF ARCHITECTURE

Lecturer II in Environmental Science

The School of Architecture needs an environmental scientist, environmental engineer, or other suitably qualified graduate, to teach the application of environmental science to building. Applications from recently qualified graduates who have an interest in this field will be welcomed.

The successful candidate will be a member of the teaching Division of Construction Technology, which is part of the Faculty of Architecture and Surveying, located at Hammersmith, London, W.6, and will also be associated with teachers of Physics and Materials Science at the Woolwich site of the Polytechnic. Personal interests and research in solar radiation or acoustics will be encouraged.

The successful applicant will teach students on full-time diploma courses in Architecture, CNA A degree courses in Surveying, and on part-time courses and will be able to contribute to planning a degree course in Architecture shortly to be submitted to the CNA A.

Salary scale: £2,515 to £3,243 plus £118 London allowance.

Further particulars and form of application may be obtained from the Secretary, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by November 16, 1973.

(1461)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PLANT SCIENCES

TWO RESEARCH ASSISTANTS are required for a project to investigate the effects of nutrient and fertiliser salts on crop plants during the early stages of development, in relation to environmental variables. The posts would suit holders of degrees in botany, soil science or agricultural science, with an interest in crop nutrition or plant physiology. Salary on the scale £1,449 to £1,818.

Forms of application and further particulars from the Registrar, The University, Leeds LS2 9JT (please quote 41A/7/D). Closing date November 30, 1973. (1515)

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF CHEMISTRY

Applications are invited for the post of POST-GRADUATE ASSISTANT, supported by the Medical Research Council, to work on the chemistry of a natural product. The work will involve synthesis and isolation procedures and the successful applicant may register for a higher degree in chemistry. Applications should be submitted as soon as possible to Professor

The Sandoz Research Institute in Vienna, Austria, is a new centre of biological research devoted to the prophylaxis and treatment of infectious diseases. It was founded three years ago by the Swiss based pharmaceutical company, Sandoz Inc.

We are now in the process of reinforcing our research effort

in the field of bacterial and fungal infections

To this end we invite the application of a

Senior Microbiologist

preferably a MD with a strong background in experimental chemotherapy and the immunology of bacterial infections.

The new member of our team would be required to take responsibility for the development of new animal models which are representative for chronic bacterial infections in humans. He would also be invited to contribute to research projects centred around the potential therapeutic and prophylactic use of bacterial antigens.

The Institute offers amenities and fringe benefits in the framework of a large pharmaceutical company. The salary will be in accordance with the importance of the job.

Applications (curriculum vitae, academic qualifications, list of publications) should be addressed to:—

**Sandoz Forschungsinstitut,
Personnel Department,
Brunner Strasse 59,
A-1235 Vienna, Austria**

(1498)

S Corporate Engineering Laboratory

Research Engineer/Scientist Biological Transformation of Energy

The Energy Section of the BSC Corporate Engineering Laboratory, located in London (Battersea), is concerned with the efficient use of energy within the Corporation, and is conducting a continuing programme of theoretical and experimental research directed towards the design and development of new and improved thermal systems and plant for steelworks application.

A vacancy exists for a Project Officer to set up and lead a project team to conduct a multi-disciplinary investigation into the recovery and use of low-grade waste heat from steelworks.

The successful candidate will be an experienced graduate who has conducted thermal research leading, ideally, to the design and development of waste heat recovery systems and who has, in addition, the ability to apply this experience to new and promising biotechnological processes. In exploring these processes, it is anticipated that regular contact will be required with industry and with University and Government research establishments. He will have an inquiring technical awareness and multi-disciplinary research interests, coupled with the ability to assume responsibility for initiating and controlling project activities from conception to completion.

If you feel your abilities and interests meet the above requirements, please write to the undermentioned for an application form, quoting reference PE-A-21:—

**The Technical Secretary,
Corporate Engineering Laboratory,
BRITISH STEEL CORPORATION,
140 Battersea Park Road, London, SW11 4LZ**

(1458)

CSIRO
AUSTRALIA

Research Scientists

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

DIVISION OF BUILDING RESEARCH

Reference Number 390/508

FIELD: RESIDENTIAL ENVIRONMENT

GENERAL. The Division has a total staff in excess of 300 including some 150 professional scientists. It undertakes research for the benefit of the Australian community into the theory, techniques and economics of building and community design, construction and materials development and is seeking an understanding of the interaction between the built environment and people. Programmes for studying the built environment are being developed in the context of both urban communities and remote settlements. The appointee will be located at Highett, Victoria.

DUTIES. To conduct research into the effects of the built environment, the relevant aspects of the natural environment and related factors of community living on residents of urban and remote settlements in Australia. This will involve the development of research techniques capable of providing guidance to physical and social planners and others determining the nature of human settlements.

QUALIFICATIONS. A Ph.D. degree or equivalent research experience, and demonstrable research ability. Applicants could be qualified in the relevant branches of psychology, sociology or geography, but scientists from other disciplines who consider that they have an appropriate background should not be deterred from applying. Experience in multi-disciplinary research teams involving social, physical and biological sciences would be an advantage.

DIVISION OF CLOUD PHYSICS

FIELD: ATMOSPHERIC PHYSICS

GENERAL. Current investigations in the Division (located in Sydney, N.S.W.) are concerned with the distribution and properties of atmospheric nuclei, basic and experimental studies of the physical processes which lead to cloud and rain and evaluation of the feasibility of modifying precipitation by cloud seeding.

Two positions are available in a group investigating the distribution and nature of atmospheric and stratospheric particles.

Reference Number 425/10

DUTIES. To investigate the size, distribution, chemical nature and sources of those particles on which cloud drops

grow; electron microscope techniques for this purpose have been developed in the Division. This will involve calibration and development of sampling techniques for use in aircraft. Field work will be necessary in areas where cloud seeding is proposed or being conducted. The contribution to cloud processes of particles produced by man's activities will also be considered.

QUALIFICATIONS. A Ph.D. degree, or equivalent qualifications, in physics, or an allied experimental field, together with demonstrable research ability. Experience in atmospheric physics, meteorology or aerosol technology would be an advantage.

Reference Number 425/11

DUTIES. To determine concentrations, size distribution and nature of all particles in the stratosphere or at clean sites in the lower atmosphere in order to provide a reference level for the assessment of changes induced by such factors as increased air traffic or industrialization. The appointee will be required to visit inland sites from which sampling balloons are released. Work on the development and calibration of suitable samples will be necessary.

QUALIFICATIONS. A Ph.D. degree, or equivalent qualifications, in physics, or an allied experimental field, together with demonstrable research ability. Experience in atmospheric physics, meteorology or aerosol technology would be an advantage.

DIVISION OF APPLIED CHEMISTRY

Reference Number 586/168

FIELD: MICROBIOLOGY/BIOCHEMISTRY ENGINEERING

GENERAL. The Division (located at Melbourne, Victoria) undertakes research into a wide spectrum of applied chemical problems and includes a section devoted to research and development of a number of novel water and waste water treatments. It operates an experimental pilot plant for the physico-chemical treatment of sewage.

DUTIES. To undertake studies in the microbiological aspects of sewage treatment processes with the aim of developing novel processes and techniques for the removal of organic material and for sterilization.

QUALIFICATIONS. A Ph.D. degree or equivalent qualification in biochemical engineering or microbiology plus experience in process studies, together with demonstrable research ability.

SALARY. Appointments will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A8,489–\$A12,932 p.a.

TENURE. Positions No. 425/10 and 425/11 are available for a fixed term of three years. The other two positions are available for an indefinite period and Australian Government Superannuation benefits are available.

APPLICATIONS. Applications should state full personal and professional details, the names of at least two professional referees, and quote the appropriate Reference Number and should reach:—

The Personnel Officer,
Australian Scientific Liaison Office,
64-78, Kingsway,
LONDON,
WC2B 6BD

by the 7th December, 1973.

Applications in U.S.A. and Canada should be sent to
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.
WASHINGTON, D.C. 20036, U.S.A.

Beecham Research Laboratories

Medicinal Research Centre, Harlow

... are shortly opening a new purpose-built toxicology block which will considerably increase facilities for toxicological and drug safety assessment. Additionally the vacation of existing premises will enable basic research projects to expand. This means we now have openings for those with specific scientific and technological expertise and those with no practical experience but a relevant academic background.

TOXICOLOGY UNIT

Toxicologists

Graduates with a special interest in the pharmacological aspects of toxicology and drug safety evaluation. Relevant qualification would be a Pharmacology Degree or M.I. Biol. backed up by experience in physiology or pharmacology—not necessarily related to toxicology or drug safety assessment. Preferred age range 24–30.

Two graduates are also required in the Animal Studies Section. Relevant degrees could be physiology, biochemistry, pharmacology or M.I. Biol. Experience in drug safety and toxicology procedures an advantage but those appointed could be new graduates in the age range 21–30.

Pathologist

With experience in the evaluation of histo-pathology from laboratory animals treated with new drugs. The successful candidate could hold a veterinary qualification or be a physiologist with training in slide reading.

Mutageneticist

A graduate in a biological discipline with a specialist interest in genetics. Some experience of testing new drugs for mutagenic potential an advantage but encouragement and specialist training will be given to increase expertise where necessary.

Research Assistants

1. Animal Studies

Minimum qualification HNC/L.I. Biol. Some experience in drug safety and toxicology procedures in a pharmaceutical

or university laboratory essential, including handling laboratory animals. Age 23–35.

2. Clinical Chemistry

Minimum qualification HNC Experience of clinical chemistry laboratory techniques essential, possibly gained in pharmaceutical laboratories studying drug safety and toxicology or in a hospital laboratory pathology department. Age 20–30.

BASIC RESEARCH-PROJECT TEAMS

Pharmacologists

To join multi-disciplinary teams of scientists and technicians seeking novel therapeutic compounds in the anti-hypertension, anti-inflammatory and gastric secretion areas.

Synthetic Organic Chemists

To work in a project group investigating compounds of potential pharmaceutical interest. Applicants must have a good honours degree, preferably with one or two years experience in the field of synthetic organic chemistry—biased, towards medicinal research. We would also be interested to hear from those currently completing Ph.D. theses.

Biochemical Pharmacologist

With a degree level training in Biochemistry and a good grounding in general pharmacology.

Competitive salaries will be paid and there are the usual benefits which are associated with a major British-based company. The Medicinal Research Centre is located one mile from Harlow New Town and combines easy access to London with proximity to pleasant countryside. Development Corporation housing may be available at economic rent to suitable candidates.

Please write, outlining your career to date, to:
John Atkinson, Personnel Officer,
Beecham Research Laboratories, Fourth Avenue,
The Pinnacles, Harlow, Essex.

1872
(1517)

BRL

CHELSEA COLLEGE UNIVERSITY OF LONDON

DEPARTMENT OF APPLIED BIOLOGY

TECHNICIAN (GRADE 3) required in the Microbiology Laboratory. Duties will include assistance in the preparation of media, reagents and cultures for undergraduate teaching, assistance in the research activities of the Microbiology Section, and the technical photography of the Department. Previous experience in microbiology (preferably bacteriology) is required. Salary scale £1,825 to £2,095 per annum (including London allowance). Application forms from Mr. K. Harris (N), Department of Applied Biology, Hortensia Road, London SW10 0QX. (1486)

RESEARCH TECHNICIAN REQUIRED IN THE Department of Plant Biology and Microbiology to assist in higher plant genetics and cytogenetics. Salary (Grade 3) £1,650 by £54 to £1,794 per annum, plus London Weighting £175 per annum. Five-day week. Five weeks (in total) annual leave—(T/JSF). Queen Mary College, Mile End Road, London E1 4NS, stating age, experience, qualifications and present work. (1487)

WINDSOR GROUP H.M.C. AREA LABORATORY KING EDWARD VII HOSPITAL WINDSOR

Applications are invited for the following posts:

(a) **DEPARTMENT OF MICROBIOLOGY:** 1. Senior Technician. 2. Technician. 3. Junior Technicians—for this and the two undermentioned departments.
(b) **DEPARTMENT OF HAEMATOLOGY:** Technician.

(c) **DEPARTMENT OF CHEMICAL PATHOLOGY:** Technician.
Good facilities for those wishing to take special Finals.

The Laboratory provides a comprehensive service for approximately 1,000 beds in the Windsor, Ascot and Maidenhead areas, and for Outpatient Clinics and General Practitioners in the area. Expansion of the Hospital Services is anticipated in the near future. The hospital is situated close to public terminal, within easy access of London by road and has its own swimming pool. Applications to the Senior Pathologist, Area Laboratory. Tel. Windsor 61424 (enquiries to Senior Chief Technician). (1508)

PHYSIOLOGIST UNIVERSITY OF TORONTO CANADA

DEPARTMENT OF OPHTHALMOLOGY RESEARCH INSTITUTE

offers a lectureship in ocular physiology. Salary \$10,000 for 12 months, renewable.
Apply: Professor J. C. McCulloch, Department of Ophthalmology, 1 Spadina Crescent, Toronto, Ontario, Canada M5S 2I5. (1472)

CHARING CROSS HOSPITAL MEDICAL SCHOOL

GRADUATE/TECHNICIAN required for a varied research programme in the Department of Obstetrics and Gynaecology, involving Haematology, and some Biochemistry and Histochemistry. Previous experience not essential. Salary £1,500 per annum, post tenable for one year in the first instance with probable extension for a suitable individual. Please apply with curriculum vitae to: The Secretary, Charing Cross Hospital Medical School, Brandenburg House, Fulham Palace Road, W6 9HH. (1474)

UNIVERSITY OF MELBOURNE
LECTURESHIPS (LIMITED TENURE)
(3) IN MARINE SCIENCE

The University, in recognizing the importance of the Marine Sciences in teaching and research, invites applications for lectureships tenable for three years in each of the fields of Marine Botany, Marine Chemistry and Marine Zoology and commencing January 1, 1974. Applicants should hold a Ph.D. or its equivalent.

The appointments will be made to the Faculty of Science and the appointees will work within appropriate Departments in the Faculty of Science and should have interests which might assist with the further development of Marine Science in the University of Melbourne. In particular they will be expected to become involved in the planning of new courses, maintain a personal research programme, and supervise research.

LECTURESHIP IN MARINE BOTANY

QUALIFICATIONS: To include postgraduate degree in Botany and research experience in Marine Botany (Phytoplankton or an allied field) and an interest in both teaching and research.

DUTIES: Primarily to initiate an undergraduate course and research in phytoplankton to be integrated with existing course in Marine Botany and with other aspects of Marine Science taught in the Science Faculty. It is expected that the appointee will engage in research and be available for limited teaching in other areas such as First Year Biology.

LECTURESHIP IN MARINE CHEMISTRY

QUALIFICATIONS: Applications are invited from candidates who have majored in Chemistry or Marine Chemistry, and who preferably have had post-doctoral research experience in one of the areas of analytical, biological, electrolyte or membrane chemistry. Preference may be given to a candidate whose research interests complement existing Departmental programmes.

DUTIES: The appointee will be expected to lecture in Marine Chemistry and supervise a practical unit in marine chemistry to undergraduate students. About half the appointee's time will be available for collaborative research in programmes in Marine Chemistry.

LECTURESHIP IN MARINE ZOOLOGY

QUALIFICATIONS: Ph.D., or equivalent, in an area of Marine Zoology, preferably Ecology, or a serious intention to specialize in that subject; experience in teaching at an advanced undergraduate level desirable; and recognized research achievement.

DUTIES: Establishment of a third-year level unit in Marine Zoology; co-ordination and participation in a general inter-disciplinary unit in Marine Ecology; and limited teaching in other areas of Zoology.

SALARY: \$A8,698 to \$11,982 per annum.

Details of application procedure and conditions of appointment may be obtained from the Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF.

Applications close on December 10, 1973.

(1514)

UNIVERSITY OF MELBOURNE
LECTURESHIP IN THE DEPARTMENT
OF PHYSIOLOGY

Applications are invited for this position.

QUALIFICATIONS: The applicant should have teaching and research experience in Physiology and a Ph.D. in Physiology, a Medical Degree or equivalent.

DUTIES: The appointee will participate in the departmental teaching activities, including the organizing and supervision of laboratory exercises for undergraduate students. It is anticipated that the appointee's research interests relate to one of the fields being studied at present in the Department. These include: physiology of the mammalian nervous system with emphasis on sensory processes, lipid metabolism and atherosclerosis, cardiovascular, respiratory and renal physiology, haematology and biomedical instrumentation.

SALARY: \$A8,698 to \$11,982 per annum.

COMMENCING DATE: March 1, 1974, or as soon as possible thereafter.

Further details may be obtained from Professor I. Darian-Smith, Department of Physiology, in the University.

Application procedure together with conditions of appointment may be obtained from the Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF.

Applications close on December 14, 1973.

(1511)

THE ROYAL VETERINARY COLLEGE
(UNIVERSITY OF LONDON)

TECHNICIAN (Grade 6) in Biochemistry required to supervise teaching and research laboratories in the Department of Physiology. Technical and administrative skills are of equal importance in this post.

Salary on scale £2,370 by £84 to £2,874 per annum.

Application to Assistant Secretary (Personnel) (N), The Royal Veterinary College, Royal College Street, London NW1 0TU.

(1513)

Opportunities Overseas

This appointment is wholly financed by the British Government under Britain's programme of aid to the developing countries.

Ghana

WEED CONTROL SPECIALIST

To initiate and implement a research programme covering forest and savanna zones. The programme will involve a detailed study of advanced weed control methods, particularly the use of herbicides in conjunction with optimal agronomic practices in the cultivation of field and plantation crops. Applicants who should normally be citizens of, and permanently resident in, the UK should have a degree with preferably postgraduate training and extensive experience in weed research. Knowledge of tropical agronomy and weed problems desirable. Appointment two tours of 18 months.

Salary, subject to UK income tax, in range of £3,000-£4,500 pa plus a variable tax free overseas allowance in range of £725-1,480 pa.

Other benefits include free family passages, paid leave, children's education allowances and free accommodation and medical attention.

For full details, application form and booklet about Ghana, please apply giving age and brief details of qualifications and experience to:—

Appointments Officer,
Foreign and Commonwealth Office,

Overseas Development Administration

Room E301/N, Eland House,
Stag Place, London SW1E 5DH

(1509)

ARCHIFAR

A Pharmaceutical Industry

has a vacancy at the new Research Laboratories in Northern Italy for a

MICROBIOLOGIST

He will be engaged in research on ANTIBIOTICS and ENZYMES. Applicants must have at least 4 years of post-graduate experience in the field. Applications which should include comprehensive curriculum vitae and addresses of two referees, should be sent to:

Archifar S.p.A., Via Trivulzio, 18, 20146 Milan, Italy.

(1387)

UNIVERSITY OF LEICESTER DEPARTMENT OF PHYSIOLOGY

SENIOR LECTURER

Applications are invited for the post of SENIOR LECTURER in the Department of Physiology (Head of Department, Professor R. Whittam, F.R.S.). Experience and an interest in teaching medical students are essential. Preference will be given to holders of a medical qualification, but other suitably qualified applicants will be seriously considered. There are excellent research facilities.

Initial salary, dependent on qualifications and experience, within the scale £4,368 to £5,496 a year, with F.S.S.U. membership.

Further particulars from the Registrar, to whom applications should be sent by December 11.

(1423)

Assistant in Regulatory Affairs Department

Smith Kline & French Laboratories Limited is a major international pharmaceutical company based in Welwyn Garden City. We now require an additional graduate to join our Regulatory Affairs Department, which is the principal interface between the company and the medicines licensing authorities.

The basic requirements are:

a good honours degree in a biological science or pharmacy with, possibly, postgraduate experience in pharmacology

the ability to present information in coherent, precise reports.

The work will entail the evaluation and editing of data from within the Company's own research and from other sources. Experience in the preparation of data for licensing bodies or experience with the requirements of the drug regulatory authorities would be a distinct advantage.

Salaries are competitive and will reflect ability and experience. Conditions of employment are in line with those expected of a large international organisation. Assistance with relocation expenses given where appropriate.

Please write giving brief relevant details to:

**The Personnel Officer,
Smith Kline & French Laboratories Limited,
Mundells, Welwyn Garden City, Herts.**

(1476)

BIOLOGICAL SCIENCES Quality Control Manager

for Flow Laboratories, Europe's leading supplier of tissue cultures, media, sera and viral diagnostic reagents. The company manufactures in sterile conditions and quality considerations are paramount. The Quality Control Manager will be responsible to the Scientific Director for implementing — and where necessary modifying — quality control procedures covering raw materials, production processes and finished goods. Candidates, probably aged 25 to 30, will be life science graduates, preferably qualified to Ph.D. level, having specialised in a relevant aspect of virology, microbiology, bacteriology or biology. Previous experience of operating quality control techniques would be an asset. Salary by agreement; excellent pension and assistance with removal to West of Scotland. Please write in strict confidence with brief career details to A.W.B. Thomson, 12 Lynedoch Crescent, Glasgow G3 6EQ.

SELECTION ● THOMSON

(1462)

Department of the Environment
Water Pollution Research Laboratory, Stevenage

Information Scientist

■ Edit and prepare technical reports ■ Prepare material for exhibitions ■ Literature searching and information retrieval ■ Answer technical enquiries.

□ Degree, HNC or equivalent in Biology, Physics, Chemistry or related subject □ Age under 27 □ Appointment as Scientific Officer (£1318-£2177) □ Ref: SA/9/HE □ Closing date 30 November 1973.
□ Application forms from Establishments Office, Water Pollution Research Laboratory, Elder Way, Stevenage, Herts.

Centre for Overseas Pest Research, London

Statistician/Biometrician

■ To work in Ecology Division ■ Advise research workers on collection and presentation of experimental data on insect and bird pests ■ Involves working abroad for at least short periods.

□ Degree, preferably in Mathematics, with training in Statistics and interest in Biology □ Interest in computer programming and building of insect population models desirable □ Age under 32 □ Appointment as Scientific Officer (£1493-£2352); Higher Scientific Officer (£2251-£2842); or Senior Scientific Officer (£2790-£3815) □ Ref: SA/5/JA □ Closing date 30 November 1973.

□ Application forms from the Establishment Officer, Centre for Overseas Pest Research, Overseas Development Administration, College House, Wrights Lane, London W8 5SJ.

Department of the Environment
Princes Risborough Laboratory

Technical Editor

■ Assist in editing publications ■ Prepare drafts for articles and press releases on the Laboratory's work (timber and related technology) ■ Arrange dissemination of research results through scientific and technical journals.

□ Degree/HNC in science or engineering □ Editing and technical writing experience and knowledge of timber technology advantageous □ Age under 27 □ Appointment as Scientific Officer (£1318-£2177) □ Ref: SA/34/HA □ Closing date 30 November 1973.

□ Application forms from Establishment Office, Princes Risborough Laboratory, Princes Risborough, Aylesbury, Bucks.

Science
group
CIVIL SERVICE

(1504)

UNIVERSITY OF YORK
DEPARTMENT OF BIOLOGY

Applications are invited for the post of TECHNICAL in the Biology Department teaching laboratories. Candidates will be responsible to the Chief Technician in the teaching laboratories and should have an Advanced City and Guilds Certificate, H.N.C. or equivalent qualification.

Salary in Grade 4 (£1,848-£2,163).

Applications to Departmental Superintendent, Biology Department, University of York, Heslington, York YO1 5DD, with the names and addresses of two referees by November 16. (1522)

UNIVERSITY OF TORONTO
DEPARTMENT OF PHYSICS

Applications are invited for a faculty position at the level of ASSISTANT PROFESSOR in the Department of Physics. Applicants should have a Ph.D. and research experience in solid earth physics. The solid earth physics group in the Department of Physics has an active and well supported research programme in geomagnetism, crustal seismology, tectonics and geochronology, and works in close co-operation with the Department of Geology. Appointment will be effective July 1, 1974.

Applicants should send curriculum vitae and names of three referees to: Professor D. J. Rowe, Department of Physics, University of Toronto, Toronto M5S 1A7, Ontario, Canada. (1439)

UNIVERSITY OF BATH
SCHOOL OF BIOLOGICAL SCIENCES

Applications are invited for a

RESEARCH ASSISTANT

to assist in an investigation, supported by the Science Research Council, into the Physiology of Lampreys. Candidates should have some experience of basic biochemical techniques and have a degree or HNC qualification. Salary range: £1,650 to £1,920. Application forms obtainable from the Registrar (S), The University, Bath BA2 7AY, quoting reference number 73/149. Closing date: December 10, 1973. (1465)

INSTITUTE OF OPHTHALMOLOGY
(UNIVERSITY OF LONDON)
EDITORIAL ASSISTANT

Editorial Assistant required by Editor of international medical abstracting journal to assist in the production of the journal. Applicants should be educated to "A" level standard. A knowledge of modern languages and an ability to type would be an advantage. Previous editorial experience not essential. Age 20 plus. Starting salary £1,554 per annum. 5-day week, 9.00 a.m. to 5.30 p.m. Four weeks annual leave.

Applications in writing should be made to: The Secretary, Institute of Ophthalmology, Judd Street, London WC1H 9QS. (1477)

BIOLOGIST

Applications are invited for a full-time opening in the Cell Biology Division for a well-trained Ph.D. interested in committing his/her efforts to developing organ culture systems to investigate the differentiation and altered differentiation of epithelial tissues in response to vitamin A, vitamin A analogues, and carcinogens.

Should have training and background in organ/tissue culture, a good basic biological training, and be acceptably knowledgeable in biochemistry. A recent Ph.D. or one with one to two years' post-doctoral training would be acceptable.

Please send recent curriculum vitae to:

Personnel Office
Southern Research Institute
2000 Ninth Avenue South,
Birmingham, Alabama 35205, U.S.A.

An Equal Opportunity Employer M/F.

(1389)

THE UNIVERSITY OF MELBOURNE

LECTURER/SENIOR LECTURER IN VETERINARY ANATOMY

in the

Department of Veterinary Preclinical
Sciences

Applications are invited for this position from graduates who have specialised in the study of morphology and are interested in teaching veterinary undergraduates in the field of gross anatomy. The appointee will be expected to assist with lecturing and practical instruction in anatomy and to engage in research in projects with anatomical implications within the departmental framework which includes physiology, biochemistry, pharmacology and developmental and microscopic anatomy.

Salary: Lecturer, \$A8,698 to \$A11,982; Senior Lecturer, \$A12,268 to \$A14,308.

Further information, including details of application procedure and conditions of appointment, is available from the Registrar, The University of Melbourne, Parkville, 3052, Victoria, Australia. Applications, referring to position 260008, should be addressed to the Registrar, and close on December 14, 1973. (1475)

UNIVERSITY OF EXETER
DEPARTMENT OF ENGINEERING SCIENCE
RESEARCH IN BIO-ENGINEERING

A research studentship is available in the Department of Engineering Science, University of Exeter. The value of the studentship is £1,063 per annum and is available for a period of three years in the first instance.

The work will be concerned with an examination of the properties of bone, bone cement and implants under various loading conditions to determine the optimum properties of bone cements and the optimum method of transmitting loads through an implant into bone.

Applications are invited from science and engineering graduates with first or upper second class honours degrees.

The applications, giving details of the candidate's qualifications and experience, and the names of two referees, should be addressed to: The Secretary of the University, The University of Exeter, Northcote House, The Queen's Drive, Exeter EX4 4QJ. (1467)

ENTERIC REFERENCE LABORATORY

Honours Science Graduate, at least 2:1, in a biological subject or a basic science; if latter, knowledge of molecular biology necessary. Work is in a research group investigating problems connected with transferable drug resistance. Post-doctoral applicants eligible. Starting salary dependent on qualifications and experience from minimum of £1,566 plus £126 London Weighting per annum (plus wage award being negotiated).

Applications with full curriculum vitae and names and addresses of at least two referees to Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. (1500)

INSTITUTE FOR MARINE ENVIRONMENTAL RESEARCH

The research programmes of I.M.E.R. are centred on ecological surveys of the open ocean, near-shore waters and estuaries, including field and laboratory studies of the factors which generate variability in ecosystems.

Applications are invited for three posts:

K—COASTAL OCEANOGRAPHER to join a group of biologists and chemists engaged in a systems study of estuarine ecology, presently in the Bristol Channel: to take responsibility for studies of circulation patterns and water budgets, including long-term, climate-induced variability. To be based at Plymouth.

QUALIFICATIONS: Degree in a physical science, preferably with relevant experience, ability in computer handling of data and a general understanding of, and sympathy with, simulation modelling techniques.

L—OCEANOGRAPHER to join a group of biologists and physicists investigating long-term trends in the plankton populations of the North Atlantic: to specialize in analysis of long-term climatic changes in the oceanic environment and in the correlation of such changes with trends in plankton populations observed from the I.M.E.R. Continuous Plankton Recorder Surveys. To be based at Edinburgh.

QUALIFICATIONS: Degree in a physical science, preferably with training or experience in physical oceanography or climatology and computerized data handling techniques.

M—ECOLOGIST for research on long-term trends in the plankton of the North Atlantic based on the Continuous Plankton Recorder Survey: to specialize in studies of variability of plankton community structure related to environmental variability. To be based at Edinburgh.

QUALIFICATIONS: Degree in a relevant biological science, and preferably with training in computer handling and analysis of data.

Grades and starting pay dependent on age, qualifications and experience. Candidates will be considered for appointment at Higher Scientific Officer/Senior Scientific Officer level (salary range £2,076 to £3,640) and exceptionally well qualified candidates will be considered for Principal Scientific Officer (£3,472 to £4,575).

Non-contributory pension scheme.

For application forms or further particulars write (specifying post K, L or M) to the Director, Institute for Marine Environmental Research, 13/14 St. James Terrace, Plymouth PL1 3AX, Devon.

Closing date: November 30, 1973.

NATURAL ENVIRONMENT RESEARCH COUNCIL. (1503)

UNIVERSITY OF SYDNEY LECTURESHIPS IN PHYSIOLOGY (TWO)

One person appointed will be required to assist in the teaching of physiology to medical, dental and science students and to take special responsibility for the development of teaching methodology including the use of audio-visual aids, programmed texts and assessment techniques.

The other will be required to assist in the teaching of medical, dental and science students and will also be required to take responsibility for the recently acquired Philips 201 electron microscope and to advise and assist other members of the department in its use.

The positions advertised are permanent, but may be filled for three years in the first instance with possibility of permanency or in certain cases return fares.

Salary range: \$A8,698 to \$A11,982 per annum.

Applications including curriculum vitae, list of publications and names of three referees by November 20, 1973, to the Registrar, University of Sydney, N.S.W. 2006, Australia, from whom further information available. Information about conditions of appointment and application procedure also available from Association of Commonwealth Universities (Appis.), 36 Gordon Square, London WC1H 0PF. (1483)

STRANGEWAYS RESEARCH LABORATORY WORT'S CAUSEWAY CAMBRIDGE CB1 4RN

Applications are invited for the post of RESEARCH ASSISTANT in the Tissue Physiology Department.

The work will be concerned with a study of the role of extracellular proteolytic enzymes in invasive human tumour growth. Applicants should have an honours degree in the biological sciences, preferably with an interest in immunology and/or biochemistry. The work will involve the use of immunological and immuno-cytochemical methods and cell and organ culture techniques.

The successful applicant will be expected to start in January 1974. The salary starts at £1,830 per annum (plus F.S.S.U.) and rises to £2,058 over 3 years.

Applications, outlining previous experience and including the names of two referees, should be sent to Dr. A. R. Poole at the above address. (1493)

NATURE

Secretary to the Editor

This is a senior secretarial position with administrative responsibilities. It would be of most interest to someone with a scientific background.

Write to the Editor, NATURE,
4 Little Essex Street, London WC2R 3LF

A SCIENTIFIC OFFICER

is required to undertake the design and layout of investigations conducted at the Board's Experimental Station, prepare working documents and subsequently process, analyse and report the data. He or she will also assist in the interpretation of the results obtained from research sponsored by the Board at other research centres and universities.

Applicants should preferably have a degree in Agriculture, Agricultural Science or related biological discipline, with experience in field experimentation and analysis of data. Knowledge of data processing techniques would be advantageous. Salary will be within the scale £2,112 to £2,745 per annum, dependent upon age, qualifications and experience, plus London allowance of £177 per annum. Pension scheme. Luncheon vouchers.

Application form from Personnel Officer, Potato Marketing Board, 50 Hans Crescent, Knightsbridge, London SW1X 0NB. (1495)

THE INSTITUTE OF PHYSICS requires an EDITORIAL ASSISTANT to join its permanent staff in Bristol

The Publishing Division of the Institute has a staff of about 60, many of whom are professionally qualified. The main activity is the publication of a range of international physics journals, and there are plans for expansion in this and related areas.

Applicants should be prepared to work steadily as a member of a small editorial team. Working conditions are pleasant, in a modern office.

Candidates should have an honours degree or equivalent in physics, mathematics or chemistry. Starting salary will be between £1,440 per annum (minimum for a recent graduate) and £1,800 per annum with regular increases to £2,340 per annum and promotion prospects to £2,940 per annum. No previous editorial experience is required. Training will be given in the basic techniques of sub-editing and proof reading, with the possibility of further training in wider aspects of publishing.

Apply to: Managing Editor, Institute of Physics,
Netherton House, 23 Marsh Street,
Bristol BS1 4BT. (1518)

CHAIRMAN—DEPARTMENT OF ANATOMY

Columbia University, College of Physicians and Surgeons, an equal opportunity employer, is seeking an individual as Chairman of Anatomy Department. Should be qualified medical scientist and experienced medical educator.

Send curriculum vitae to: Myron Wlnick, M.D., Chairman, Search Committee, Institute of Human Nutrition, 511 West 166th Street, New York, New York 10032. (1289)

JUNIOR TECHNICAL OFFICER REQUIRED AT Pollards Wood Research Station of the Institute of Cancer Research, Chalfont St. Giles, Bucks., to take part in a research programme on mutagenic effects of carcinogens. B.Sc. or H.N.C. in a biological subject. Experience in genetics, cytology or cell biology desirable. Further study possible. Starting salary £1,400 per annum in a scale extending to £2,073, according to qualifications, age and experience.—Apply in duplicate, giving the names of two referees, to the Secretary, 34 Summer Place, SW7 3NU, quoting Ref. 301/B/490. (1489)

PLANT PATHOLOGIST

Applications are invited for the permanent post of Plant Pathologist in the Plant Pathology Division of the Ministry of Agriculture, to conduct research on fungal diseases of potatoes.

The person appointed may be required to undertake teaching duties in the Department of Mycology and Plant Pathology, Faculty of Agriculture and Food Science, Queen's University, Belfast.

Appointment may be at Senior Scientific Officer, Higher Scientific Officer or Scientific Officer level.

The necessary qualifications are:

Senior Scientific Officer—normally over 25 and under 32 years of age with a good Honours Degree in a scientific or agricultural discipline pertinent to plant pathology with at least 4 years relevant postgraduate experience. Salary scale £2,615–£3,640.

Higher Scientific Officer—under 30 years of age with a good Honours Degree as above and at least 2 years relevant postgraduate experience. Salary scale £2,076–£2,667.

Scientific Officer—under 27 years of age with a good Honours Degree as above. Salary scale £1,318–£2,177.

Grading and entry point to salary scales will be related to qualifications and experience.

Please write or telephone for an application form and further information quoting Ref. SB 234/73/N to: Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232-44300, ext. 26). Completed applications must be returned to arrive not later than 27th November, 1973.

**NORTHERN IRELAND
CIVIL SERVICE**

(1497)

Plant Physiologist— Liberia

Circa £6,200

The Firestone Plantations Company who operate in Liberia the largest single plantation in the world require a plant physiologist to assist in the continuous development programme of improving the quality and yield of the product. Candidates should have a good degree in botany, forestry or agriculture and good knowledge of hevea culture, tapping systems and plant stimulation. Salary and local allowances are payable in U.S. dollars and will not be less than £6,200 per annum. Home leave each year, subsidised housing, free medical and educational facilities are among the many fringe benefits provided. Interviews are being arranged for mid-November and applicants should write in confidence to:

**Staff Personnel Manager,
Firestone Tyre & Rubber Co. Ltd.,
Great West Road,
Brentford, Middx.**

(1482)

**CENTRAL PUBLIC HEALTH
LABORATORY
COLINDALE AVENUE, LONDON NW9 5HT**

Honours Science Graduate, microbiology, for position of **QUALITY CONTROLLER** in Media Production Department. The successful applicant will be responsible for routine testing and control of bacteriological and virological media; also the development of new media. Experience in microbiology with particular reference to medical bacteriology advantageous. Participation in some administration duties is expected. Salary according to age, qualifications and experience. Applications with full curriculum vitae to Personnel Officer at above address.

(1499)

UNIVERSITY OF KHARTOUM SUDAN

Applications are invited for the post of **PROFESSOR/SENIOR LECTURER** in the **DEPARTMENT OF ANIMAL PRODUCTION**, Faculty of Agriculture. The applicant should be a holder of an M.Sc. or Ph.D. in the field of Animal Nutrition and Feeding and have a good experience with feed-lot fattening and meat quality assessment. He will be offered the post of a Senior Lecturer or Professor depending on his qualifications, publications and experience. Salary scale: Professor £53,600 per annum; Senior Lecturer £52,400 to £52,800 per annum. The British Government may supplement salary in range £1,300 to £1,800 per annum (sterling) for married appointee or £800 to £1,000 per annum (sterling) for single appointee (normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; various allowances; superannuation scheme; annual overseas leave. Detailed applications (2 copies) including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than November 29, 1973, to the Personnel Secretary, University of Khartoum, P.O. Box 321, Khartoum, Sudan. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars are available from either address.

(1488)

UNIVERSITY OF OTAGO DUNEDIN, NEW ZEALAND ASSISTANT LECTURER IN MICROBIOLOGY

The Council of the University of Otago, Dunedin, New Zealand, invites applications from science graduates for an appointment as Assistant Lecturer in the Department of Microbiology in the Medical School. This appointment is for up to three years. Salary: according to qualifications and experience—\$NZ4,660 to \$5,839 per annum.

Further information may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, from Professor J. A. R. Miles, Department of Microbiology, University of Otago Medical School, P.O. Box 913, Dunedin, New Zealand, or from the Registrar of the University, P.O. Box 56, Dunedin, New Zealand.

Applications close in New Zealand and in London on December 1, 1973.

(1512)

McMASTER UNIVERSITY VIROLOGIST

A position is available for a Virologist at the Assistant or Associate Professor level. The appointee will be part of a viral oncology group being formed at McMaster University as well as a member of the Department of Biology. His/her research interests should be the molecular biology and/or genetics of animal viruses. His/her primary responsibility will be research and supervision of graduate students.

Applicants should send their curricula vitae and the names of three referees to the Chairman, Department of Biology, McMaster University, Hamilton, Ontario L8S 4K1, Canada, to arrive no later than January 15, 1974.

(1381)

UNIVERSITY OF MANCHESTER DEPARTMENT OF ZOOLOGY RESEARCH ASSISTANT IN CYTOLOGY

Applications invited for this post (funded by the O.D.A.) for research connected with tsetse fly and trypanosome control, involving the investigation of DNA/RNA synthesis during gametogenesis, oogenesis and vitellogenesis, and the cytogenetics of species, hybrids and radiation induced mutants. Post tenable until September 30, 1976, with an initial salary up to £2,058 per annum rising to £2,388 per annum. F.S.S.U.

Detailed applications, with names of two referees, should be sent to Dr. D. I. Southern, Department of Zoology, The University, Manchester M13 9PL, as soon as possible.

(1404)

**ST. THOMAS'S HOSPITAL
MEDICAL SCHOOL
(UNIVERSITY OF LONDON)
LONDON SE1 7EH**

Applications are invited from suitably qualified graduates for appointment as ASSISTANT LECTURER in Medical Genetics. This newly established post will be held within the Department of Anatomy. The successful candidate will be expected to take part in teaching medical genetics, to assist in building up a cytogenetics unit giving a service to the hospital and to pursue a research interest. Appointment is for three years in the first instance with a possible extension to four years; salary, according to age, qualifications and experience, but within the range £1,929 to £2,223 per annum plus £162 per annum London allowance and superannuation with F.S.S.U. Some postgraduate experience, with or without a Ph.D. is desirable but not essential. Applications giving full details to be sent to School Secretary. (1494)

**AGRICULTURAL RESEARCH COUNCIL
INSTITUTE FOR RESEARCH ON
ANIMAL DISEASES
COMPTON, BERKSHIRE
HELMINTHOLOGIST**

Applications are invited from graduates with at least an upper second class honours degree and a minimum of two years' research experience for a vacant post in the Institute's Department of Parasitology. Preference may be given to a candidate who has obtained a Ph.D. degree. The successful candidate will be required to conduct research on nematodes of farm livestock and initially will be expected to study nematode/bacterial interactions. The appointment will be in the H.S.O. (£2,076 to £2,667)-S.S.O. (£2,615 to £3,640) scales according to qualifications and experience, plus a 4% per cent allowance to offset F.S.S.U. superannuation contributions. Applications, accompanied by a curriculum vitae and the names and addresses of two referees, should be submitted to the Institute Secretary, citing vacancy No. 153, by November 30, 1973. (1496)

**UNIVERSITY OF OTAGO
DUNEDIN, NEW ZEALAND
LECTURER OR SENIOR LECTURER
IN NUTRITION**

Applications are invited for the position of Lecturer or Senior Lecturer in the Department of Nutrition in the School of Home Science, University of Otago.

Salary: Lecturer: \$NZ6,575 to \$8,343 per annum; Senior Lecturer: \$NZ8,489 to \$NZ10,846 per annum with a bar at \$NZ9,963 per annum. (Note: \$NZ100 equals approximately £61 sterling; \$US147; SA100.)

Applicants should be graduates in Science with specialisation in biochemistry, physiology, nutrition or chemistry; Food Sciences or in Home Science.

Further particulars are available from the Secretary-General, Association of Commonwealth Universities (Apps.), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close in New Zealand and London on February 15, 1974. (1510)

**UNIVERSITY OF OXFORD
TRINITY COLLEGE
JUNIOR RESEARCH FELLOWSHIP
IN BIOLOGICAL OR MEDICAL
SCIENCE**

The College invites applications for a Junior Research Fellowship in a field of science related to biology or medicine, tenable for three years from October 1974. The Fellowship is intended for work of post-doctoral character; preference will be given to candidates under 30 years of age. Further details are available from the College Secretary. The closing date for applications is January 5, 1974. (1516)

**MEDICAL RESEARCH COUNCIL NATIONAL
Institute for Medical Research. BIOCHEMIST.** Applications are invited for a postdoctoral appointment on the staff of the DIVISION OF MOLECULAR PHARMACOLOGY to work on enzymological and structural aspects of membrane bound receptors. The appointment will be for three years in the first instance. Incremental salary according to age and qualifications within the range £2,058 to £4,548 per annum plus £162 per annum London allowance. F.S.S.U. provision. Applications, giving the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA. (1519)

MALE GRADUATE (OR H.N.C.) BIOLOGIST required to join a team working in respiratory physiology and inhalation toxicology. Studies are being made into the effects on Primates and Rodents of exposure to cigarette smoke, air pollutants, and therapeutic aerosols. Salary range £1,400-£2,800 depending upon experience.—Application form from: John Halliday, Personnel Officer, Huntingdon Research Centre, Huntingdon PE18 6ES, quoting Reference 279. (1448)

Pharmaceuticals Division

Technical Assistant

We are looking for someone with experience of the microbial field (virology and/or bacteriology) to work in our Virus Section of Biology Department. The main responsibility of the job is to develop potential antiviral drugs. In addition, the job involves some diagnostic work in connection with animal health, and also fundamental research into the control of human and animal virus disease.

The job would suit someone with a technical background (IMLT), but paper qualifications are less important than a lively mind and a willing and constructive approach to the problems of the job.

The Pharmaceuticals Division is very attractively situated in rural North Cheshire, within easy reach of main road and rail routes. There is a wide range of country and town housing within 20 minutes drive to cater for most tastes. Conditions of service, career opportunities, and assistance given to married men in moving home are designed to attract and retain staff of high calibre.

Applications in writing, giving brief details of age, qualifications and experience, should be addressed to:

**M F Losse Personnel Officer
Imperial Chemical Industries Limited
Pharmaceuticals Division
Merseydale Park
MACCLESFIELD Cheshire SK10 4TG.**

(1505)

1946 1967 1968 1969 1970 1972

**COLÁISTE NA HOLLSCOILE GAILLIMH
(University College Galway)**

TECHNICIAN

The Department of Obstetrics and Gynaecology has a vacancy for a Technician.

Salary within the region of £1,614 by £54 to £1,830.

Minimum qualifications: Intermediate Certificate of Institute of Medical Laboratory Technology, Intermediate Certificate of City and Guilds of London, Intermediate Technological Certificate of Department of Education or equivalent.

Applications, stating age, experience, qualifications and the names of two referees, should be sent, as soon as possible, to Professor of Obstetrics and Gynaecology, Regional Hospital, Galway.

(1459)

**UNIVERSITY OF NATAL
DEPARTMENT OF GEOLOGY, DURBAN**

Applications are invited from suitably qualified persons for appointment to the post of:

LECTURER IN ECONOMIC GEOLOGY

The salary scale attached to the post is:

R4,800 by R300 to R6,900 per annum

plus 15 per cent pensionable allowance on basic salary.

The commencing salary notch will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus up to R260 for married men and R130 for women and single men is payable, subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, King George V Avenue, Durban, with whom applications, on the prescribed form, must be lodged not later than December 18, 1973, quoting Reference Advice 93/73. (1502)

Microbiologist

John Wyeth & Brother Limited, an expanding pharmaceutical company situated at Havant in Hampshire have an immediate vacancy for a Microbiologist in their Quality Control Laboratory.

The selected candidate should hold a B.Sc. Honours degree in Microbiology. This post calls for a high degree of initiative and would suit a young person looking for an opportunity to participate in the management of a major department.

Excellent terms and conditions, non-contributory pension and life assurance scheme in operation. Assistance with re-location expenses available.

Please write to Cameron Wolstenholme, Personnel Controller, John Wyeth & Brother Limited, Huntercombe Lane South, Taplow, Maidenhead, Berks, SL6 0PH.

(1525)

Wellcome

Scientific Administrator

Up to £4500

This is a new appointment in the Department of Virology at the Wellcome Research Laboratories at Beckenham in Kent. The post involves overall responsibility for the general administration of this large department, including budgeting, staff recruitment and control, financial records and procurement of supplies. Close liaison with service departments such as Finance, Engineering, Personnel and supplies will be necessary. Also involved will be the provision of technical and scientific support to the Departmental Quality Controller.

Candidates, probably aged 35 or over, must have extensive administrative experience. A scientific background probably in some area of biology would be a considerable advantage.

The Laboratories are situated in attractive parkland surroundings within easy reach of London and pleasant residential areas. Salary is negotiable, depending on age and experience, up to £4500. In addition the company offers excellent conditions of employment including pension and life assurance schemes.

Please write, giving brief details of qualifications and experience to

The Personnel Manager,
The Wellcome Research Laboratories,
Langley Court,
Beckenham BR3 3BS.

(1492)

UNIVERSITY OF LEICESTER DEPARTMENT OF GEOLOGY

Applications are invited for the post of ELECTRONICS TECHNICIAN, Grade 6, in the Geophysical section of the above department. The person appointed will be responsible for the maintenance and development of a wide range of laboratory and field equipment. He must be prepared to participate in field work programmes in the U.K. and overseas. A sound knowledge of electronics is essential and familiarity with Geophysical equipment would be an advantage. Supervision of and liaison with other technicians essential and some administrative duties are involved.

Minimum qualifications: H.N.C. or equivalent with 10 or more years' experience in related fields. Salary within the range £2,370 to £2,874. Applications should be made direct to the Chief Technician, Department of Geology, University of Leicester, University Road, Leicester LE1 7RH, giving full details of qualifications, experience, age and the names of two referees by November 30, 1973. (1490)

RESEARCH ASSISTANT UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

Graduate with biochemical and biological background required for research involving cell culture and amino acid analysis in the study of inherited disease. Post tenable from January 1, 1974, for 1 year in the first instance with possible extension for a further 2 years. Salary scale £1,470 to £1,704 plus £126 London allowance, starting point according to experience. Enquiries to Dr. D. P. Brenton, Department of Human Metabolism, U.C.H. Medical School, University Street, London WC1E 6JJ. Telephone 01-387 9300, ext. 166. (1491)

UNIVERSITY OF ADELAIDE PROFESSOR OF ZOOLOGY

Applications from scholars with interests in any field of zoology for appointment in succession to Professor H. G. Andrewartha. The Professor will be Chairman of the Department for an initial term of five years when the position of the Chairmanship will be reviewed.

SALARY: \$A19,102 a year with superannuation on the F.S.S.U. basis.

FURTHER INFORMATION: Potential candidates are invited to obtain from the Secretary-General, Association of Commonwealth Universities (Appus.), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University, a Statement about the Chair and formal terms of appointment. Any further information desired may be obtained on request to the Registrar.

APPLICATIONS (in duplicate) giving the particulars listed in paragraph 9 of the Statement should reach the Registrar of the University, G.P.O. Box 498, Adelaide, South Australia, 5001, not later than December 15, 1973. (1484)

WESTFIELD COLLEGE (UNIVERSITY OF LONDON) ELECTRON MICROSCOPE UNIT

requires a TECHNICIAN GRADE 5 to take charge of the day-to-day running of the Electron Microscope suite and also to take an active part in training Postgraduates in Electron Micrography. The salary will be on the scale £2,007 to £2,382 plus London Allowance per annum. Applicants should hold an I.S.T. diploma in Electron Micrography and be able to use the AG1.801B microscope. Applicants without this qualification but willing to undergo training will also be considered but will be appointed on a lower grade.

Applications, giving full details and the names of two referees, should be sent to the Personnel Officer (N), Westfield College, Kidderpore Avenue, Hampstead, London NW3 7ST, by November 20, 1973. (1451)

UNIVERSITY OF LEICESTER DEPARTMENT OF PHYSIOLOGY LECTURER

Applications are invited for the post of LECTURER in the Department of Physiology (Head of Department, Professor R. Whittam, F.R.S.). An interest in teaching medical students is essential, and possession of a medical qualification desirable, but other suitably qualified applicants will be seriously considered. There are excellent research facilities.

Initial salary, dependent on qualifications and experience, within the scale £1,929 to £4,548 a year, with F.S.S.U. membership.

Further particulars from the Registrar, to whom applications should be sent by December 11. (1422)

ROYAL POSTGRADUATE MEDICAL SCHOOL. GRADUATE SCIENTIFIC OFFICER/TECHNICIAN required in Immunoassay Laboratory of the Endocrine Unit. Candidates should possess good biochemical and isotope qualifications and laboratory experience, preferably in a similar post. Salary according to qualifications and experience in range £1,600 to £2,300.—Applications to the Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, DuCane Road, W12 0HS, quoting Refer-

RESEARCH CHEMIST —Radiochemicals

The Union International Co. Ltd. wishes to engage a young Research Chemist, aged about 28/30, for the Radiochemical Section at the St. Albans Research Centre.

Experience in synthetic radiochemical techniques is essential, and candidates should be sufficiently well qualified and mature to justify appointment as Radiological Safety Officer.

The bench work will primarily involve the preparation of labelled bile acids and sterols and some experience of steroid synthesis would, therefore, be very desirable.

The salary is negotiable according to qualifications and experience, and there is a Contributory Pension Scheme. Some assistance would be given for re-location.

Applications, giving full personal and career details, should be sent to the Staff Manager (AD 5765), 14 West Smithfield, London, E.C.1.

(1507)

UNIVERSITY OF NATAL DEPARTMENT OF GEOLOGY, PIETERMARITZBURG

Applications are invited from suitably qualified persons for appointment to the post of

LECTURER OR JUNIOR LECTURER

The salary scales attached to the post are:

R4,800 by R300 to R6,900 per annum
R3,600 by R150 to R4,650 per annum

plus 15 per cent pensionable allowance on basic salary.

The commencing salary notch will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus up to R260 for married men and R130 for women and single men is payable, subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, King George V Avenue, Durban, with whom applications, on the prescribed form, must be lodged not later than December 18, 1973, quoting Reference Advice 94/73.

(1501)

M.R.C. CLINICAL RESEARCH CENTRE (NORTHWICK PARK HOSPITAL) WATFORD ROAD, HARROW MIDDLESEX HA1 3UJ

Applications are invited for the post of RESEARCH ASSISTANT to Sir Peter Medawar, joining a small group of workers mainly studying transplantation and tumour immunity. Salary according to experience and qualifications. F.S.S.U. benefits.

Applications by November 30 to Sir Peter Medawar, from whom further particulars may be obtained. Ref. G1. (1506)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING (UNIVERSITY OF READING) BACTERIOLOGY DEPARTMENT

A SUPERVISOR is required for a section responsible for preparation of bacteriological media. Applicants should have had sound training in chemistry or bacteriology.

An appropriate degree, H.N.D., H.N.C., or equivalent is required. The appointment will be in the Scientific Officer grade within a scale of £1,318 to £2,177 per annum according to qualifications and experience. Superannuation, with an allowance to offset contributions. Apply on forms obtainable from the Secretary, National Institute for Research in Dairying, Shinfield, Reading RG2 9AT. Quote reference 73/46. (1471)

UNIVERSITY OF KEELE DEPARTMENT OF PHYSICS

Applications are invited for the post of LECTURER tenable from October 1, 1974, to take part in the establishment of ELECTRONICS as a Principal undergraduate course. Experience in an applied area of electronics (e.g. in the telecommunications industry or in medical electronics) could be an advantage. Salary scale: Lecturer, £1,929 to £4,548. Further particulars and application forms from the Registrar, The University, Keele, Staffs, ST5 5BG, to whom they should be returned by January 8, 1974.

(1470)

RESEARCH TECHNICIAN

required to assist with a project involving Genetics, Biochemistry and Virology in the Department of Plant Biology and Microbiology. Salary (grade 2B) £1,524 by £54 to £1,794 per annum plus London Weighting £175 per annum. Five-day week. Five weeks (in total) annual leave. Letters only to Assistant Secretary (Establishment) RT/DH, Queen Mary College, Mile End Road, London E1 4NS, stating age, experience, qualifications and present work. Closing date November 10, 1973. (1485)

TECHNICIANS (2) REQUIRED IN BACTERIOLOGY DEPARTMENT for research with group investigating immune defences to bacterial infections. Salary according to age, experience and qualifications within scale £1,440/£2,292 per annum plus £126 per annum L.W.—Apply, The Secretary, St. Mary's Hospital Medical School, Paddington, W2 1PG. (1455)

FELLOWSHIPS AND STUDENTSHIPS

UNIVERSITY OF MELBOURNE JUNIOR RESEARCH FELLOW IN MARINE BACTERIOLOGY in the SCHOOL OF MICROBIOLOGY

Applications are invited for this position.

QUALIFICATIONS: The successful applicant should hold a Ph.D., have had research experience in marine or aquatic bacteriology, and be capable of independent research.

DUTIES: The Fisheries and Wildlife Department of the State of Victoria is co-ordinating a Pollution Survey of Port Phillip Bay. The Junior Research Fellow will study the bacterial flora of different representative environments in the Bay, to evaluate the effects of current practices of water management. These results will be co-ordinated by the Fisheries Department with studies of other parameters and used to construct a mathematical model of the Bay. The bacteriological research will be done in the School of Microbiology, and technical assistance will be provided; facilities for field work will be provided through the Fisheries and Wildlife Department.

SALARY: \$A7,556 in the first instance, with annual increments to \$A8,128. Limited assistance is available for travel to Australia for an overseas applicant.

The successful applicant would be required to begin duties in January 1974 and the grant is available for 3 years from that date. Further information can be obtained from Dr. N. F. Millis, School of Microbiology, University of Melbourne, Parkville 3052, Victoria, Australia.

Details of application procedure are available from the Registrar, University of Melbourne, Parkville 3052, Victoria, Australia. Applications, referring to Position No. B/2/73 and including the names of at least two referees, should be addressed to the Registrar and close on December 5, 1973. (1426)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF CLINICAL CHEMISTRY

Applications are invited from BIOCHEMISTS, preferably post-doctoral, for the post of RESEARCH FELLOW/ASSOCIATE to investigate the control of protein synthesis in human and animal tissue by hormones and other agents. The project is supported by a grant from the M.R.C.

Salary in the range £1,569 to £2,718, depending on qualifications, age and experience, plus F.S.S.U.

Further particulars may be obtained from Dr. D. R. London, Queen Elizabeth Hospital, Birmingham B15 2TH, to whom applications (3 copies), naming three referees, should be sent by November 30, 1973. (1479)

UNIVERSITY OF GLASGOW POST-DOCTORAL RESEARCH FELLOWSHIP IN BIO-ORGANIC CHEMISTRY

Applications are invited from post-doctoral bio-organic chemists for a research position (tenure 1 to 3 years) under an M.R.C. project grant to Drs. C. J. W. Brooks (Chemistry) and W. A. Harland (Pathology) for biochemical studies of human atherosclerosis. The research depends on the refined use of modern chromatographic techniques. Experience in lipid or sterol chemistry, and in micro-analytical methods, would be advantageous. The post will fall vacant on December 1, 1973, and the initial salary will be in the range £1,929 to £2,223 per annum for suitably qualified applicants.

Applications, with curriculum vitae, citing two referees, should be sent to Dr. C. J. W. Brooks, Chemistry Department, The University, Glasgow G12 8QQ. In reply please quote Ref. 3381M. (1481)

THREE POST-DOCTORAL FELLOWSHIPS IN THE EARTH AND PLANETARY SCIENCES

The Lamont-Doherty Geological Observatory of Columbia University invites scientists interested in any field of the earth and planetary sciences to apply for the following Fellowships.

Two Post-Doctoral Fellowships, each awarded for a period of one year (extendable to two years in special instances) beginning in September, 1974, with a stipend of \$12,000 per annum. One Senior Post-Doctoral Fellowship, the stipend and term of the award to be arranged to suit the special requirements of the successful applicant. Completed applications are to be returned by February 15. Announcements will be made March 31.

Application forms may be obtained by writing to the Director, Lamont-Doherty Geological Observatory, Palisades, New York 10964. (1473)

THE UNIVERSITY OF SHEFFIELD

POSTDOCTORAL RESEARCH FELLOWSHIP

Department of Chemical Engineering and Fuel Technology

Applications are invited for a Postdoctoral Fellowship financed by an industrially sponsored grant to carry out research on ignition in gases containing spontaneously flammable substances. The appointment will be for one year starting as soon as possible.

Details from Dr A. N. Hayhurst, Department of Chemical Engineering and Fuel Technology, University of Sheffield, Mappin Street, Sheffield S1 3JD. Please quote Ref. R89/G. (1460)

KENT EDUCATION COMMITTEE MEDWAY AND MAIDSTONE COLLEGE OF TECHNOLOGY

SCIENCE DEPARTMENT

Applications are invited for the post of

POST-DOCTORAL RESEARCH FELLOW

to work on the surface properties of manganese dioxide. The project will involve the use of radioactive isotopes and high vacuum techniques and will be carried out in new, well-equipped laboratories. Experience in surface studies of powders is desirable.

The appointment, in the first instance, will be for two years with a possible extension to a third year; and the fellow appointed may be required to teach up to six hours per week.

Commencing salary: £1,660 per annum.

Applications, including curriculum vitae, to the Principal, Medway and Maidstone College of Technology, Horsted, Maidstone Road, Chatham, Kent. (1464)

UNIVERSITY OF GLASGOW DEPARTMENT OF NATURAL PHILOSOPHY RESEARCH FELLOWSHIP SOLID STATE PHYSICS GROUP

A post-doctoral research fellow is required to join a group concerned with structural studies of the surface of liquids by high energy reflection electron diffraction. At a later date this work may be extended to investigations of solid state surface phenomena. Experience of U.H.V. and/or electron diffraction methods would be desirable but not essential.

Salary scale for the post will normally be within the range £1,900 to £2,500 per annum, according to age and experience. Tenure two years on appointment, with possible renewal for a further year. F.S.S.U. benefits.

Applications, stating age, academic qualifications, research experience and the names of two referees, should be submitted not later than November 30, 1973, to Professor R. P. Ferrier, Department of Natural Philosophy, University of Glasgow, Glasgow G12 8QQ. In reply please quote Ref. 3380M. (1480)

UNIVERSITY OF NEWCASTLE UPON TYNE RIDLEY FELLOWSHIP IN AIR AND WATER POLLUTION DEPARTMENT OF CIVIL ENGINEERING

Applications are invited, from persons who have shown themselves able to carry out original research, for the Ridley Fellowship in Air and Water Pollution tenable in the Public Health Engineering Division of the Civil Engineering Department. The Fellowship is financed by the British Steel Corporation to promote research on some aspect of air and water pollution. Applicants should normally have a higher degree (preferably Ph.D.) in a relevant branch of Science or Engineering.

The normal tenure of the Fellowship will be three years from October 1974 (or such earlier date as may be arranged). The stipend for the first year of the Fellowship will be £1,929, for the second year £2,058 and for the third year £2,223 (plus F.S.S.U.).

Further particulars and application forms (which must be returned by December 31, 1973) may be obtained from the Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU. (1468)

GRANTS & SCHOLARSHIPS

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF CHEMICAL ENGINEERING ESSO RESEARCH STUDENTSHIP

Applications are invited from graduates in pure or applied science for the Esso Research Studentship, of the value of £695 a year with remission of certain fees, tenable in the Department of Chemical Engineering. The person appointed will study the effects of electric fields upon suspensions of particles and may register for a higher degree. Applications, including a curriculum vitae and the names and addresses of two referees, should be sent to Professor J. D. Thornton, Department of Chemical Engineering, University of Newcastle upon Tyne, Merz Court, Claremont Road, Newcastle upon Tyne NE1 7RU. (1469)

LECTURES AND COURSES

UNIVERSITY OF LONDON: A COURSE OF two lectures entitled "Brown Adipose Tissue: A Source of Extra Heat Production" will be delivered by Professor Olov Lindberg (Stockholm) at 5.30 p.m. on November 20 and 22 at University College, Anatomy Lecture Theatre, Gower Street, W.C.1. Admission free, without ticket.—Academic Registrar. (1466)

PROGRESS IN WATER TECHNOLOGY

Volume 1 **Applications of New Concepts of Physical-Chemical Wastewater Treatment**

Edited by W. W. Eckenfelder and L. K. Cecil

CONTENTS: Municipal waste treatment by physical-chemical methods; Physicochemical systems for direct wastewater treatment; Advanced waste treatment at Alexandria, Virginia; Physical/Chemical treatment design for Garland, Texas; Ultrahigh rate filtration of municipal wastewater; Interrelationships between biological treatment and physical/chemical treatment; Tertiary treatment—the corner stone of water quality protection and water resources optimization; The effective utilization of physical-chemically treated effluents; Upgrading existing wastewater treatment plants; Some problems associated with the treatment of sewage by non-biological processes; The applicability of carbon adsorption in the treatment of petrochemical wastewaters; Treatment of wastes from metal finishing and engineering industries; Physical and biological interrelationships in carbon adsorption; Regeneration of activated carbon; Principles and practice of activated carbon; Automation and control of physical-chemical treatment for municipal wastewater; Recent studies of calcium phosphate precipitation in wastewaters; Logical removal of phosphorus; Phosphorus removal by chemical and biological mechanisms; Use of surface stirrers for ammonia desorption from ponds; Dewatering physical-chemical sludges; Disposal and recovery of sludges from physical-chemical processes; The role of freezing processes in wastewater treatment; Wastewater treatment through electrochemistry; Ultrafiltration and microfiltration membrane processes for treatment and reclamation of pond effluents in Israel; Membrane equipment selection for the Must Hospital water recycle system; Comparative cost of tertiary treatment processes; Process selection and cost of advanced wastewater treatment in relation to the quality of secondary effluents and quality requirements for various uses; Interrelationships between fresh water and wastewater plants; How usable is present technology for removing nutrients from wastewater.

400 pages £7.00 hard cover March 1973

Volume 2 **Phosphorus in Fresh Water and the Marine Environment**

Edited by S. H. Jenkins and K. J. Ives

CONTENTS: Natural phosphate sources in relation to phosphate budgets; a contribution to the understanding of eutrophication; Significance of man-made sources of phosphorus: fertilizers and farming. The phosphorus involved in agricultural systems and possibilities of its movement into natural water; The significance of man-made sources of phosphorus: detergents and sewage; Phosphates in sewage and sewage treatment; Phosphorus in industrial water; Phosphorus in primary aquatic plants; Phosphorus in marine zooplankton; Role of phosphorus in eutrophication and diffuse source control; Significance of phosphorus in lakes and coastal water sediments and benthos; The acceleration of the hydrogeochemical cycling of phosphorus; Phosphorus in chemical and physical treatment processes; The role of phosphorus in the growth of *Cladophora*; Eutrophication and Lough Neagh; Stimulation of phytoplankton growth by mixtures of phosphate, nitrate and organic chelators; Soil and fertilizer phosphorus in the Irish ecosystem; Treatment in municipal plants: innovations for removal of phosphorus; Chemical pretreatment before biological treatment in sewage plants; A new method of removing phosphorus to produce a ready fertilizer; Experience with algal blooms and the removal of phosphorus from sewage; Environmental impact of detergent builders in California waters; An improved method of phosphorus analysis in sea water; Problems in the analysis of phosphorus compounds; Safety evaluation of substitutes for phosphates in detergents; Soluble phosphate removal in the activated sludge process; The microbiology of an activated sludge waste-water treatment plant chemically treated for phosphorus removal; Efficient biological waste-water purification is a precondition for chemical phosphate removal

357 pages £8.00 hard cover June 1973

Volume 3 **Water Quality: Management and Pollution Control Problems**

Edited by S. H. Jenkins

CONTENTS (Partial): Legal and administrative problems; Training and education; Wastewater quality criteria; New analytical techniques; Virus problems in wastewater disposal; Problems of developing countries and arid zones; Low cost waste treatment systems; Municipal sewage treatment: Problems of design, operating and maintenance; Municipal sewage treatment: Problems of small communities; Packaged treatment; Industrial wastewater; Synthetic detergents environmental considerations; Renovation and reclamation of domestic and industrial waste waters; Ecological assessment of marine pollution

The Ionisation of Carbon Acids

J. R. Jones

November 1973, viii + 236 pp., £4.80
0.12.389750.5

Too frequently in the past research workers interested in a reaction have tended to concentrate their attention on a particular aspect of the problem. Here, however, the problem is approached in its entirety. Carbon acids are the subject matter of the book and the kinetic and equilibrium aspects of the ionisation process are investigated in detail using a variety of experimental techniques. The work's scope is wide-ranging, and, as such, can be read with profit both by the physical chemist with an interest in the study of reaction kinetics and by the physical organic chemist from a mechanistic point of view, as well as by the organic chemist concerned with the use of carbanions in chemical syntheses.

Physico-chemical Properties of Nucleic Acids Volume 3

Electron microscopy, intra- and intermolecular interactions, radiation effects in DNA cells, and repair mechanisms

edited by Jules Duchesne

November 1973, xvi + 220 pp., £5.00
0.12.222903.7

Physico-chemical Properties of Nucleic Acids aims at providing thought-provoking material for research scientists, whether they are biologists, chemists or physicists. At the same time, this publication forms a highly comprehensive and up-to-date source of information and reference that should prove to be of great value to graduate students in these fields.

Contents: Electron microscopy of nucleic acid molecules. Renaturation of DNA in the absence and in the presence of Cu^{++} ions. Interactions in nucleic acids. The polymer and salt induced condensation of DNA. The interactions of nucleotides with bovine pancreatic ribonuclease. The measurement of radiation-induced strand breaks in the DNA of mammalian cells. Stability and evolution of DNA from the point of view of molecular radiobiology. Author index. Subject index.

Number 4

Chemical Analysis of Organometallic Compounds Volume I

T. R. Crompton

December 1973, approx. 270 pp., £5.80
0.12.197301.8

Interest in organometallic compounds is increasing throughout the world, and hitherto no book dealing exclusively with the analysis of the organometallic compounds of all the elements has been published. The author set out to rectify this situation by compiling a timely reference book which takes into account the international literature on the subject up to 1972. This book (the first of three volumes) deals with the compounds of lithium, sodium, potassium, copper, silver, gold, beryllium, magnesium, calcium, zinc, cadmium, mercury, boron, gallium and thallium.

The Fine Structure of Algal Cells

John D. Dodge

November 1973, approx. 270 pp., £6.00
0.12.219150.1

The aim of this book is to provide a comprehensive review of the structure of eucaryotic algal cells as revealed by electron microscopists over the past twenty or so years. An extensively illustrated work, abounding with numerous micrographs and diagrams, many of which have not been published before, it is the first book to cover the structure of all the main organelles found in algal cells. As such, it should prove of particular value to researchers and university students, especially advanced undergraduates and postgraduates within the fields of freshwater and marine biology.

Essays in Chemistry Volume 5

edited by J. N. Bradley, R. D. Gillard and R. F. Hudson

November 1973, x + 150 pp., £2.50
0.12.124105.X

This highly praised series is valuable both to students and to practising graduate chemists. Undergraduates can gain helpful background coverage of subjects normally omitted or only briefly mentioned in standard textbooks, while specialists will find the opportunity to keep abreast of recent developments particularly useful.

Contents: Neville Jonathan: Photoelectron spectroscopy. M. A. D. Fleundy and K. P. Lawley: Potential energy surfaces and collision processes. M. Spiro: Interfacial catalysis and inhibition of solution reactions. R. Ramage: Alkaloid biosynthesis. C. M. J. Stirling: Elimination reactions.

For a descriptive leaflet on any of the above titles, please write to the publishers.

Calculator convenience, computer facilities

Calculators are undeniably easy to operate: you enter the data, select the operation, and the machine gives the answer. With a normal computer you have to have everything perfect to start with — otherwise all you get is an error message.

The WANG 2200 is a calculator with all the facilities of a computer: a programming language—BASIC, peripherals, lots of storage. It is self-contained and modular — you can start with a low-cost system and add storage and peripheral facilities as you need them.

The statistics calculator with "BASIC"

We made the WANG 2200 easy to use. Programming is in BASIC, the simplest, most understandable language there is. You input a BASIC word with one single, silent keystroke. You see the calculation progressing on the screen, you check, correct, and learn more about your program. Any error is marked by a coded arrow.

The BASIC is standard Dartmouth, so most existing programs will work. And WANG supplies a range of

statistical, mathematical and technical programs free of charge. With the peripherals available you can build the system you need.

Up to 32K of computing power

The WANG 2200 has up to 32K bytes of program storage. Disk storage for 5 million characters is available. And if necessary, it can be used as a terminal. Whatever power your problem needs, the WANG 2200 can provide it.

Plus alphabet work

Any computer can work with numbers. The WANG 2200 processes letters and symbols too.

Wang, the specialists in scientific calculators

Wang laboratories have been making electronic calculators for more than ten years. We made many of the innovations that made programmable calculators possible, gave them peripherals; increased their power. WANG calculating systems are sold and serviced in more than 40 countries.

- Spina bifida**—An antenatal diagnosis in the Lewis rat—MACRI, EVANS (Nassau County Medical Center New York) and JOSHI (Downstate Medical Center, New York)

Diamond or Abrasive Wheel Cut-off Machine **MODEL GSP 210**

Cuts Rock, Refractories Ceramics Glass or Metals

High speed vibration free taper roller bearing spindle.
Standard Cutting Wheels, 8" diameter $\times$ 1/16" or 1 mm wide.
Area of cut 5" $\times$ 2 1/2" — Drive flat nylon belt.—
Dimensions—length 30", width 28", height 16". Wt. 1 cwt.

CUTROCK ENGINEERING CO. LTD.

Phone 01-346-5978

35 Ballards Lane, London N.3

A simple to operate machine with application in all fields where hard materials are cut.

The vice unit will grip either regular or irregular specimens, and has a detachable vee jaw for clamping rods, cores or tubes.

Coolant pipes on both sides of the cutting wheel supply ample cooling during cutting. The machine can be supplied with a settling tank and pump unit if required.

Additional equipment—cross slide with 2 1/2" movement.

Vice with Vee Location

are you using stable isotopes?

Everyone connected with modern research should send for details of these remarkable Isotope Labelled Compounds.

Isocommerz have perfected a selection of Isotope Labelled Compounds which are proving to be of tremendous benefit in Chemical Research, Engineering, Biology, Medicine, and particularly in Agriculture.

If you are not already taking advantage of this highly successful technique, post the coupon today for descriptive literature.

Isocommerz have a sales and advisory service at C.Z. Scientific Instruments Ltd., who are the sole distributors of their products in the U.K.

A Medal-seeker's Guide

ALL that most scientists get for their hard work is a pay-packet and a vague feeling of satisfaction that one or two of nature's secrets have revealed themselves. Higher rewards, however, are available—medals and prizes. Since the cash is often not insignificant, we provide as a service to our readers a guide to landing some of Britain's plum rewards that they may have overlooked or thought inaccessible. There are no preliminary qualifications and in general the nationality of potential recipients is not taken into account in making awards. The selection of winners is entrusted to the Royal Society whose yearbook provides our information. As *Nature* goes to press, this year's winners are announced, so there are twelve months to make an impact before the next award. The most recent winners are not included in the statistics, which cover the last twenty years and may be helpful as a guide to prospects.

Copley Medal, 1731, silver-gilt. From legacy of Sir Godfrey Copley, Bt., F.R.S. (1653–1709). Annual. £100 added. An additional £1,000 comes from a Jaffé prize. Nobel laureates will recall that they are not eligible for Jaffé prizes, but for them £1,000 is available from 'another source'.

Given annually to the author of research published by the Society deemed 'deserving of that honour'. In the middle of the nineteenth century the medal was "recognized as the 'palm and laurel' of science" (*Nature*, 174, 1034; 1954) and thirty-two of fifty awards between 1851 and 1900 went to foreigners.

To two Foreign Members in the last twenty years, otherwise to Fellows of the Royal Society, generally of twenty years' standing.

Rumford Medal, 1800, silver-gilt. By Count Rumford, F.R.S. Biennial. £200 added.

Given to the author of the most important discovery in any part of Europe in Heat or Light.

To a Dutchman in 1964, otherwise to Fellows on each occasion in the last twenty years.

Royal Medals, 1825 and 1965, gold. Three available. Annual. No money.

Given for the most important contributions in pure and applied science published in Her Majesty's Dominions.

Of forty-eight recipients, forty-six were already Fellows. Helpful to have been one for at least ten years.

Davy Medal, 1877, bronze. Of obscure origin believed to be connected with pawning of Sir Humphry Davy's tableware. Annual. £200 added.

Given for the most important discovery in chemistry in Europe or Anglo-America.

Not much good chemistry outside Britain these days. Of last twenty recipients, one Swiss, two American and seventeen Fellows of the Royal Society.

Darwin Medal, 1890, silver. Biennial. £200 added.

Given for work of acknowledged distinction in the field in which Charles Darwin laboured.

No limitation of nationality or sex. One Foreign Member, nine Fellows in last ten awards. All male.

Buchanan Medal, 1897, silver-gilt. Quinquennial. £200 added.

Given for distinguished work in Hygienic Science or Practice.

No limitation of nationality or sex. Two of last four winners were not Fellows, but all were male.

Sylvester Medal, 1901, bronze. Triennial. £200 added.

For the encouragement of Mathematical Research, irrespective of nationality (sic).

Last six recipients should have needed no encouragement to carry on, as they had been Fellows for on average twenty years.

Hughes Medal, 1902, silver-gilt. Given by Professor David E. Hughes, F.R.S. Annual. £200 added.

Given for original research, particularly in Electricity and Magnetism.

No restriction on nationality or sex, but the last twenty recipients have all been male Fellows.

Leverhulme Medal, 1960, gold. To mark the tercentenary of the Society. Triennial. £500 added.

Given for the most significant contribution in chemistry or engineering.

In 1966, Sir Alec Issigonis won this medal before being made a Fellow.

Mullard Medal, 1967, gold. Annual. £1,000 added.

The only medal for which Council formally takes outside advice.

Given for an outstanding contribution to science, engineering or technology leading directly to national prosperity in the United Kingdom.

Not awarded to a Fellow since 1967.

100 Years Ago

WE learn from the Journal of the Society of Arts, that one of the first results in the rise of the price of coal has been the formation of a company in France, whose object is to utilise the power of the ocean tides on the French coast by proper machinery. The first experiment is to be made at St. Malo, where the tide rises nearly 80 ft., and overflows many square miles of flats.

From *Nature*, 9, 54, November 20, 1873.

Analysis of Cause—Long Cut to Prevention?

"Abatement is the aim of medicine . . . even the concept of causation can, on occasions, be dispensed with in considering abatement strategies."

Dr J. H. Renwick of the London School of Hygiene and Tropical Medicine urges the need for more emphasis on preventative thinking in framing hypotheses in medical science.

ALTHOUGH in biomedical research prevention of a disease is customarily considered complementary to its cause, most of the scientific working hypotheses are framed around testing the supposed cause directly. In some circumstances, however, there are advantages in framing hypotheses around prevention.

I shall consider first the circumstances in which the classical causal hypothesis is more or less adequate. These arise either when a disease situation occurs naturally that superficially resembles a laboratory experiment or when a true experiment is possible in an animal that is acceptable as a valid analogue of man.

The thalidomide incident is an example of the natural or at least unplanned experiment. When thalidomide was taken by pregnant women and a defined range of otherwise rare malformations was observed in many of their offspring but not in the offspring of other women, the hypothesis was

proposed that thalidomide was at least a contributory cause of these malformations in humans. Indeed, for any new ailment (disease, malformation or injury), it is simple and effective to state a proposition in the causal mode. As in a classical experiment, a known background situation is modified and an effect produced.

An animal experiment with thalidomide would be an example of the other situation (of adequacy of a causal hypothesis) but only when the test animal is trusted as a valid analogue of man. Rhesus monkeys and certain marmosets are so trusted; the malformations produced in them by this drug are almost identical with those in man. A causal hypothesis even for man, being therefore indirectly testable, can usefully be proposed.

Need for Abative Hypotheses

The position is different for ailments to which man has been subject for a long time and for which no convincing animal analogue is available. Unfortunately, we are in the habit of constructing causal claims about even these ailments although the relevant experiments to test the claims directly would usually be unethical. The causal experiments are therefore impracticable except in imagination. In a 'thought experiment' of this sort, an artificial base-line for the population has to be created. In one example, it could involve the (imaginary) absence of refined sucrose. This basal situation would then be modified (in imagination) by the addition of sucrose and various alimentary disorders would ensue. Such at least is the experiment that seems to be suggested by a causal claim that sucrose is an important factor in the cause of colonic diverticulosis, for example. The hypothesis cannot be tested directly because it is nearly always unethical to increase the risk of ailment in a real experiment.

If we can overcome the habit of allowing cause to dominate our thinking, we have a very simple way of bypassing such a problem. This is to perform a real intervention experiment on a part of the population with its present, known burden of disease. This basal situation is then modified—by some procedure such as reduction of intake of refined sucrose. The degree of abate-

ment of the disease is then the outcome of the experiment. With such an experiment in mind, a preventative hypothesis can be formed that is in principle testable, and there are usually no major ethical objections to an experiment of this sort. Further, the statement can be framed briefly yet accurately in terms of deviation from the present state because the 'present state' is known widely enough for it to require, in many cases, no detailed description. Many intervention experiments of exactly this type are done. The change that I am suggesting is that they should be acknowledged as testing preventative statements and not causal ones.

Preventative statements, when confirmed, will sometimes summon up practical measures to control disease. Any such measure—it may be preventative or therapeutic or both—will be called 'abative' as its purpose is to produce some abatement of the ailment and of its burden to the individual and to society.

Non-reciprocal Relationship between Cause and Abative

Wherever a necessary-and-sufficient abative measure exists there must, in principle, be a corresponding necessary-and-sufficient cause and *vice versa*. The search for cause or abative then comes to much the same task. But the relationship between cause and abative is not always so exactly reciprocal. For instance, a sufficient abative is one that removes a necessary cause. A somewhat oversimplified example of a 'sufficient abative' would be the banning of rye cultivation to prevent poisoning by the ergot fungus, for which rye is the preferred host. The corresponding causal statement is that rye is the 'necessary cause' of ergot poisoning. As in this example, so in general—an abative measure that has the property of sufficiency but not of necessity is the counterpart of a cause that is necessary but not sufficient.

The degree of reciprocity is also limited in a more subjective way. Even though abatatives, like causes, do interact, the percentage abatement of a disease incidence by a single manipulation is an unambiguous and complete concept. By contrast, the concept of the percentage effect of a single cause is more likely to be misleading unless the inter-

actions with other causes are fully specified. Specifying these interactions by the disclaimer—other things being equal—is rarely adequate.

Few such difficulties apply to statements or hypotheses on abatement. The effects of single causes or abatements are best expressed as percentage change from the initial situation. The effects (causal or abative) may sum to several times the incidence of the disease. This is not awkward if it is abative effects that are being summed since each is operative only potentially and mainly in the future. We are not surprised at the existence of alternative means of prevention nor at the possibility of their interacting, so when the sum exceeds 100% effectiveness, we are not disturbed. But there is a seeming absurdity in the statement, say, that 50% of the present incidence of a disease is caused by each of three factors, x , y , z . For the claim to be explicit, interactions or options must be invoked because, obviously, the realised effect of the three factors combined does not exceed the present overall incidence.

As already noted, intervention studies of abative measures are already an established part of epidemiological practice. For example, there have been non-smoking studies, breathalyser studies, and, on the positive side, fluoridation studies. But the conceptual framework has not been adequately spelled out to my knowledge. In some intervention studies, by a curious inversion, the investigators even imply that causes are being studied rather than abatements. The distinction is worth making as it reflects a difference. Abatement is the aim of medicine; the study of causation of an ailment, say, in experimental animals, is frequently a useful intermediate but may not be an essential one in all cases. Even the very concept of causation can, on occasion, be dispensed with in considering abatement strategies.

Remaining Problem Diseases are a Selected Sample

I suggest that if neither causes nor abatements are yet known—and I shall call such an ailment a problem ailment—causation is probably complex. The more complex the causation, the more likely it is to be currently unknown. In tackling such a problem ailment, then, we would be wise to turn at least some of our attention from causes to abatements. For example, the causal mechanism of carcinoma of the colon is unknown and probably complex. From its geographical distribution the simple and testable abative measure of a high residue diet has been proposed. From past neglect, simple abatements like this

have not always been adequately excluded.

Advantages of Abative Statements

For old-established conditions, three major advantages of abative compared with causal statements have so far been mentioned—direct testability on the human species itself; expressibility in simpler terms; and the opportunity to include a quantitative component that expresses the percentage of prevention anticipated.

This last advantage is well illustrated in the case of road accidents. We should like to make statements such as "20% of accidents in the United Kingdom are caused by alcohol", but such statements are intrinsically misleading because of the interactions: practically no cause operates in isolation. An abative statement that the introduction of the breathalyser laws in the United Kingdom reduced the accident rate by a certain percentage is simpler and open to a smaller range of interpretations.

This example introduces another important advantage of abative propositions. They are directly relevant to the achievement of human goals such as the partial prevention of accidents, and so are directly relevant to decision making in public and private life. The quantitative aspect is the most important in this context, as the predicted advantage has to be balanced against the cost of introducing the abative measure.

It is at least arguable that if the observed association between smoking and lung cancer had led to an abative rather than a causal claim, society's 20 yr delay in taking action would have been shorter. The claim would have been directly confirmed by the results now available of non-smoking intervention studies and the question of the identification of the presumed carcinogen(s) could have been deferred. Further, the genetic red herring would have been more clearly recognised for what it is—a matter of intellectual interest but with little practical relevance, in this instance, in decision making.

Perspectives on Causation and Abatement

The properties of abative statements are so attractive that we need to ask why they are rarely made. After all, if prevention of disease is an aim of medicine, why have we departed so completely from the folklore mode of expression exemplified by 'an apple a day keeps the doctor away'? The historian might well find an influence of the philosophy of non-medical science—

the dominance of how (does it happen) over how not. Waddington in *The Scientific Attitude* roughly defined science as "the organised attempt of mankind to discover how things work as causal systems". Perhaps the absence of specific mention of abatement in such definitions has been taken to imply that abative statements are less scientific than causal ones, despite the fact that, for both types, the "criterion of truth is experimental" and objective.

Alternatively, did the current emphasis on causation spring from the need of the legal system to apportion blame? Or, equally plausibly, was the need to study epidemics more pressing than the need to study the less dramatic non-epidemic state? The manifest success of laboratory methodology in so many non-human fields undoubtedly played a large part in establishing the habit of thinking in the causal mode. We correctly believe that we have not understood anything at a fundamental level unless we have understood the mechanism of causation. And we often think (incorrectly) that such understanding is a prerequisite of wise action. Kant knew better—that "it is often necessary to make a decision on the basis of knowledge sufficient for action but insufficient to satisfy the intellect".

It is true, even today, that wise action can occasionally be based at least temporarily on empirical knowledge alone and there are many examples of this from the past. From the time of Admiral Wager, scurvy was controlled in the Navy by the provision of citrus fruits before ascorbic acid was known to be a vitamin. Penicillin was used effectively, even before its mode of action was understood; and tobacco avoidance dramatically reduces bronchocarcinoma incidences although we still do not know how.

Decision-making in medicine is more directly concerned with prevention and treatment rather than causation, so we should often express claims in terms of abatement rather than causation as at present. A few scientists disagree. They argue that causation and abatement are simply converse concepts and, at the same time, that one is scientific, the other empirical. Both arguments are rather shallow assessments. Abatement is not always the simple converse of causation. Further, an abative statement can be as scientific and testable experimentally as any other. It may even be just as possible to discover general laws concerning abatement as laws concerning causation.

Abative and causal hypotheses are not mutually exclusive. Indeed, there is a one-to-one relationship between them. The abative statement is usually simpler in practice. This is particularly true for complex problems. And most real-life problems are complex.

NEWS

Slower and Cooler in the United States

by our Washington Correspondent

IN the next few months, nearly every American is going to be brought face to face with the energy crisis, for it is now clear that there may be rationing of petrol and heating oil, closing of some schools and offices, shorter working hours and even a few cold homes. Apart from the inconvenience and upset that these situations will cause, their overall effect will be to force Americans to cut back on their use of energy—not just this winter, but permanently. And that will require some rather fundamental changes in a society that has been mindlessly consuming energy at a staggering rate.

Last week, President Nixon went on television to warn the country of the gravity of energy shortages that are likely to develop in the United States this winter, and to outline emergency measures that his Administration wants to take to deal with the situation. The reaction has been startling. Newspapers have been filled with little else—for a time the energy crisis even eclipsed Watergate as the focus of national attention—state governors have been announcing measures to curtail consumption of energy in their territories, and a few people have turned down their central heating. On Capitol Hill, committees have been stung into action and have passed legislation to give the President sweeping powers to force a reduction in the use of energy throughout the country. And the Stock Exchange has seen the biggest drop in share prices in 11 years.

The root cause of the impending shortages is that the growth in energy consumption in the United States has for years been outstripping the growth in supply. But the situation has been blown into crisis proportions by the embargo that Arab countries have placed on their oil exports to the United States, an action which will strip 2 million barrels of oil a day off the supply. The Arab cutoff, together with shortages that were developing in any case, could result in oil supplies falling short of demand by 17% when winter finally arrives. The problem, however, is that the shortages will not be evenly distributed, for it is predicted that the gap could reach an incredible 40% in the Northeast, an area which relies heavily on imported oil.

That is the prospect which caused President Nixon last week to deliver his third energy message to the American public so far this year. Unlike the pre-

vious messages, which have been concerned chiefly with increasing energy supply, and which have paid only scant lip service to the need for reducing demand, the latest effort was concerned almost exclusively with emergency measures that must be taken to decrease consumption of energy. The message came too late, and it was only forced by what President Nixon referred to as "the most acute shortages of energy since World War II", but nevertheless it represents a fundamental break with the Administration's previous attempts to deal with the energy crisis.

What Nixon is asking, in short, is for Congress to give him broad emergency powers to force people to curtail their energy appetites, and he is also appealing to the American public to act voluntarily.

Among the measures outlined in his message are the following:

- The Administration wants the power to order neon lights and ornamental lighting to be turned off, a measure which would have the welcome effect of getting rid of some of the neon nightmares that encircle so many American cities.

- President Nixon is requesting authority to force shops to close early, to require speed limits to be lowered on all roads, and to impose emergency taxes on consumption of natural gas and on excessive uses of electricity.

- He wants Congress to pass a bill authorising the use of daylight savings time (the equivalent of British Summer Time) throughout the year—a measure which could save up to 3% in electricity consumption, particularly in the northern areas which are most affected by lack of fuel.

- Finally, he is asking for broad authority to allow power plants to be exempt from air pollution regulations, so that they can burn coal and oil containing relatively large quantities of sulphur.

Those measures all require Congressional approval, but the Administration already has powers to force other changes, and it is using them. Regulations are being drawn up to prevent factories and power stations from switching from coal to oil, and the Administration is also putting pressure on electricity producers to convert power plants from oil to coal. The White House says that 46 plants can be converted within two months, at a saving of nearly half a million barrels of oil a day. The number of commercial jet flights in the United States has been reduced by the

Federal Aviation Administration, and Nixon decreed that thermostats be turned down in federal buildings. He also appealed for central heating to be turned down in private homes, for cars to be driven at speeds less than 50 m.p.h., for more use of mass transit, and for more car pooling.

Scarcely were the words of exhortation out of President Nixon's mouth when Congress was galvanised into unprecedented action. Senator Henry M. Jackson, chairman of the Senate Interior Committee and the most influential member of the Senate on energy matters, rammed a bill through his committee, after a day of hearings in a cool committee room, and the House Commerce Committee also expects to get a bill passed this week. Thus Congress is likely, by the end of next week, to have given President Nixon most of the powers he requested.

The emergency measures proposed by Nixon seem tougher, at least if implemented, than the British government's proposals announced on Tuesday in the face of a crisis exacerbated by a miners' overtime ban.

But will they be sufficient to cope with the situation? By all accounts they will not, and the Administration is developing plans to ration petrol and fuel oil if the need arises. For one thing, the measures announced last week will rely heavily on public cooperation and voluntary compliance, and for another, some of them have come too late to be effective. For example, the proposal to convert power plants from oil to coal—a fuel which the United States has in abundance—is likely to be stymied by the fact that coal production is already taking place at maximum capacity, and thus it is unlikely that coal output can be increased in time to meet a new surge in demand. Moreover, according to the White House's most optimistic forecasts, the proposals will cut demand for oil by some 2.3 million barrels a day, a figure which is well short of the predicted gap between supply and demand of three million barrels.

Thus, senior Administration officials are warning that it is likely that oil and gasoline rationing will have to be brought in before the winter has ended. Moreover, the problems will not disappear at least until the end of the 1970s when the Alaska pipeline will be bringing crude oil to the lower states. This winter is therefore likely to mark the end of an era of cheap, bountiful energy in the United States.

ENVIRONMENT

Environmental Protection

by our Washington Correspondent

THE House Appropriations Committee has handed both the Environmental Protection Agency and the National Academy of Sciences a political hot potato which could prove embarrassing. The committee passed a bill which includes \$5 million for the EPA to let a contract with the academy to carry out a massive study of the EPA's programmes and past decisions. That provision was eventually passed by the House of Representatives and the Senate, and it was signed into law at the end of last month. If the academy agrees to accept the contract, it will undertake one of the biggest and most difficult studies it has ever been involved with, and it will also run the risk of being used by hostile Congressmen as a weapon in their campaign to emasculate the EPA.

The appropriations bill itself carries the bare statement that \$5 million be provided for the academy to study the EPA, but the House appropriations committee report spells out the nature of the study in some detail. The committee suggests that the study should involve an estimate of the costs of pollution abatement over the next 10 years and that it should include an analysis of the costs and benefits of the pollution control programme—an analysis which should bring in social and economic factors.

The committee also propose that the academy be given the task of examining the costs and benefits of automobile emissions controls, the extent to which environmental regulations have contributed to the energy crisis, and the effect on agricultural productivity of various decisions to ban pesticides. Virtually every one of those topics has already been the subject of intensive study and heated debate, and there are many who find it difficult to see what new insight the academy might be able to bring to the matter.

Why was the provision put into the bill? The answer, in short, is that the EPA is unfortunate enough to have its budget scrutinised by the agriculture subcommittee of the House Appropriations Committee, and many powerful members of the subcommittee, being closely allied with farming interests, regard the EPA with about as much affection as they do the boll weevil. The chairman of the subcommittee, Jamie Whitten, a conservative Democrat from Mississippi, makes no attempt to conceal his contempt for the EPA. Last week he told the House of Representatives that the agency has contribu-

ted to the energy crisis, increased the costs of food production, increased the danger to human health by banning DDT, and put American agriculture at a competitive disadvantage.

Thus the committee is looking to the academy to provide intellectual support for its complaints about the EPA, which is an unenviable position for the academy and for the EPA to be placed in.

SOUTH EAST ASIA

North Vietnam Appeal

by our Washington Correspondent

THE Scientists' Institute for Public Information (SIPI), a public interest organisation, has launched an appeal in the scientific community for help in repairing some of the destruction caused by US bombs, herbicides, shells and other weapons in Southeast Asia. The immediate goal is to establish a Research Institute for Agricultural Botany in North Vietnam—a project which has been specifically requested by North Vietnamese scientists to help revegetate rural areas which are extensively littered with bomb craters.

According to Dr Barry Commoner, past president of SIPI, the appeal will serve the dual purpose of alerting US scientists to the post-war situation in North Vietnam and of informing the US public of the need to provide aid to all of Indochina. This is a promise which in fact was made by President Nixon during the cease-fire negotiations but which has since fallen into political disfavour.

The idea for the agricultural research institute stems from a visit to North Vietnam made in July this year by two American scientists with the support of SIPI. Dr E. W. Pfeiffer, a zoologist from the University of Montana, and Dr Arthur Westing, a botanist from Windham College, Vermont, returned with reports of devastation on a scale which Dr Westing said last week was "almost unbelievable". He said that they were rarely out of sight of bomb craters, even in the most rural areas of North Vietnam, and since more than 90% of the population is directly engaged in agriculture, Dr Westing pointed out that the greatest need for aid lies in rehabilitating the rural areas.

The SIPI appeal started this week with a letter sent by Dr Commoner and Dr Arthur Galston, professor of botany at Yale University, to some 10,000 scientists asking for aid in establishing the research institute, for scientific books and journals to be sent to North Vietnamese scientists and for equipment for the institute. Dr Galston said last week that \$100,000 will be enough to start the institute off, and that SIPI is hoping to get some of the money from

institutions and foundations. He reckons that sufficient cash and equipment should be available by April 1974 to send a small team of US scientists to North Vietnam to work in the research institute. In addition, SIPI has arranged to ship scientific books and journals to South Vietnam by way of Dr Philip Harvey, of St Stephen's Hospital in London.

OTA

Daddario Appointed

MR EMILIO Q. DADDARIO has, as expected, been appointed the first director of Congress's new Office of Technology Assessment. The appointment puts Daddario in charge of a body which he is largely responsible for setting up, and brings him back to Capitol Hill three years after he left the House of Representatives to make an unsuccessful bid for the governorship of Connecticut.

A lawyer by training, Daddario was elected to Congress in 1958, and in 1963 he became the first chairman of the subcommittee on Science, Research and Development. Under his stewardship, the subcommittee rapidly established itself as the focal point for discussion of science and technology policy issues in Congress. It also rather grotesquely revamped the National Science Foundation by making its top officials direct Presidential appointments and enabled the NSF to sponsor applied research. The subcommittee began hearings on research into environmental problems before the environmental bandwagon had even begun to move, and drew up the legislation which eventually led to the establishment of the Office of Technology Assessment.

Daddario's appointment was confirmed when the OTA board met early in November—its first meeting since the office finally got some funds to begin work (see *Nature*, 246, 6; 1973). Next step is to appoint a deputy director and an advisory council. The most likely candidate for deputy director is Daniel V. Simone, a former member of the defunct Office of Science and Technology, who is now on the staff of the NSF's Office of Science and Technology Policy. There should be little problem in finding good staff for the OTA—some 3,500 people have applied for jobs there, even though none has been formally advertised.

Short Notes

CSII on Ice

THE Centre for the Study of Industrial Innovation is in danger of dying from neglect. Negotiations between the centre's directors and the Cranfield Institute of Technology, which it was hoped would lead to the centre becoming a department of industrial innovation at the institute, have scarcely moved in the past nine months.

A recent meeting between Mr George Teeling-Smith, the centre's director, and Dr Henry Chilver, the Vice-Chancellor of Cranfield, means that discussions are still continuing, but the centre has effectively been out of operation since January of this year.

Mr Teeling-Smith said this week that it is "disappointing that it is taking so long" for any changes to take place. "We have lost so much impetus that effectively we will be starting from scratch again." At present CSII has nothing to do except sell back copies of its reports on industrial innovation, which include an assessment of the spin-off benefits from Concorde, an appraisal of the industrial research associations and the publication of the results of the Project Sappho studies on industrial innovation undertaken at the University of Sussex.

Dumping at Sea

A BILL to control dumping at sea has just been introduced to parliament. To date dumping has been limited by voluntary agreements between industry and government. Over the past seven years this has been quite effective but the bill will formalise the voluntary arrangement, making it necessary to acquire a licence to dump any material in the sea, and introducing heavy penalties for offences.

If the bill is passed Britain could be the seventh country to ratify its signature to the Oslo convention agreed in February 1972, which dealt with dumping in the north-eastern Atlantic. This convention requires ratification by seven countries to come into force. The bill will also enable Britain to ratify the London convention, concluded in December 1972, which was a global convention on similar lines to the Oslo convention. This requires ratification by fifteen countries to come into force, and Britain will probably be only the third country to ratify it. It is not, however, as immediately important to British fishing as the Oslo convention, which is concerned with the sea around the British Isles.

The basic determinant on which the decision to grant a licence will be based is the effect of the dumped material on fish. Certain substances which persist in the environment are blacklisted,

and licences for their dumping will never be granted. These include mercury, cadmium, and DDT. For dumping of other materials, including arsenic, lead and fluorides, a special licence is required, and the materials must be dumped in deep water, at least 150 nautical miles from land. Factors such as the concentration and form of the material and the area in which it is to be dumped will be taken into account in the issuing of all licences.

Dumping at sea is responsible for only 5-10% of shore-generated marine pollution. The main sources, streams and pipelines, are not affected by this bill, but will be dealt with in another bill to be published shortly, concerned with many forms of pollution including atmospheric and noise pollution. Neither does the present bill cover atomic waste, which was dealt with by the act of 1969, nor with pollution from ships, which was discussed last month in a convention in London.

Solar Energy in Australia

AUSTRALIA is expanding its interest in solar energy business with some enthusiasm. Last week a Solar Energy Studies Unit was formed by CSIRO under the direction of Mr R. N. Morse, formerly chief of the CSIRO Division of Mechanical Engineering, and immediate past president of the International Solar Energy Society.

CSIRO has had an interest in solar energy for almost twenty years, and solar heating of water is already in use to the extent of saving Australia 5,000 tonnes of coal a year. Solar heated air is also used in some industrial drying processes, while experimental timber drying kilns are already being tested.

The new unit will look at the most promising applications of solar energy for Australian conditions. Feasibility studies of short and long term projects will be undertaken, focusing current CSIRO fundamental work on solar energy collections, heat storage media, energy measurement and thermal transfer problems.

Mr W. L. Morrison, Australia's minister for science, announcing the appointment said that "the use of solar energy on a wide scale for domestic and industrial heating could help substantially to offset increased costs of fossil fuels in the future".

Developing Research

THE National Research Development Corporation is alive, well and even flourishing. This is the message contained in the corporation's annual report published last week (available free from NRDC, 66 Victoria Street, London, SW1).

The NRDC has come in for some criticism recently, particularly at the

hands of the Select Committee on Science and Technology which recommended that the corporation's structure needed "urgent financial review". This criticism was included in the select committee's report (published in September) on the closure of Tracked Hovercraft Limited, an NRDC subsidiary.

Dr Basil Bard, the corporation's managing director, said last week that the forecast for the future is encouraging with a net surplus for 1972-73 reported of £529,000 compared with £178,786 the previous year. The total income of the corporation went up from £7.4 million to £8.7 million.

One of the problems which the corporation is faced with, according to the report, is that of "maintaining in industry, in the universities and in other sources of invention, a knowledge of the corporation's existence and of the facilities it is able to provide for promoting innovation in industry".

Dr Bard said that in the past year uncertainty about the corporation's future had been replaced "by an increased awareness of the need for a body like the corporation, which has encouraged us in our belief that we have an important part to play in providing financial aid for the development and commercialisation of significant UK innovation". This, however, does not take any heed of the select committee's views.

Comet Kohoutek Disaster?

DR D. W. DEWHIRST of the University of Cambridge warned a meeting of the Royal Astronomical Society last week that members should be cautious in their public statements about Comet Kohoutek. Little is known about the factors that govern a comet's brightness, he said, and the prediction that Kohoutek will be a bright object in daylight may be over-optimistic. According to his calculations the brightest that the comet will be as viewed from Britain is magnitude -3 (on January 3) which is about as bright as Venus. Perhaps Dr Dewhirst has recalled that the failure of the Leonid meteor shower to live up to expectations in 1899 was described by the meteor scientist C. P. Olivier as "the worst blow ever suffered by astronomy in the eyes of the public".

More Mobility

SIR HERMAN BONDI's task force to encourage the mobility of scientists is nearing the end of its appointed task. Its report is being written at present and will be submitted to the Lord Privy Seal at the end of the year or in January.

There is no news of what the report contains but it is highly unlikely that the work started by the task force will be allowed to come to an end with the publication of the report in the Spring.

NEWS AND VIEWS

Changing View of Operator-Repressor Interactions

ONE of the most critical steps in the development of theories of gene control was the concept that some sequences of DNA may function not by their transcription into RNA and subsequent translation into protein sequences, but rather by serving as signals which are recognised by protein molecules acting as regulators or enzymes of gene expression. Elucidation of the mechanism of such protein-DNA interactions has become a principal aim of current research, in particular concerning the promoter sequences recognised by RNA polymerase and the operator sequences recognised by repressor proteins. The two systems which have proved particularly productive, the lactose operon of *Escherichia coli* and the early development of phage lambda, now seem likely to present very different pictures of repressor-operator interactions.

Operators have in general been thought of as rather short sequences of DNA; a consensus of opinion which is presently evolving is that they comprise, or at least include, symmetrical sequences of base pairs. A sequence of the order of twenty base pairs with features of symmetry seems, for example, to constitute the operator of the lactose operon. But the most recent work of Maniatis and Ptashne, reported on page 133 of this issue of *Nature*, replaces the idea of a single short sequence with the concept that in lambda the two operators may each comprise more complex structures, capable of recognising several repressor molecules.

The two lambda operators comprise sequences of DNA to which the lambda repressor protein binds to maintain the phage in an inactive state, by preventing transcription. Repressor binding to the 'left' operator prevents synthesis of the RNA corresponding to gene *N* immediately to the left of O_L and repressor binding to the 'right' operator similarly prevents transcription of gene *toI* lying immediately to the right of O_R . In the experiments which they now report, Maniatis and Ptashne take advantage of the techniques reported earlier this year by Pirrotta (*Nature new Biol.*, **244**, 13; 1973) for isolating the lambda operators. Radioactively-labelled lambda DNA, sonicated to yield fragments of molecular weight $3-6 \times 10^5$, is bound to the lambda repressor protein and, in several subsequent steps, the sequences of DNA not protected by the repressor are degraded with DNase and the operator sequences are retrieved by binding the repressor-operator complex to nitrocellulose filters. Since the yield of protected DNA is twice as great with wild type lambda DNA as with a mutant possessing only one operator, both of the operators of lambda can be isolated in this system.

In early experiments, the fragment of DNA protected by repressor corresponded to some twenty base pairs in length. This is much larger than had been anticipated, because in its active dimer form the repressor protein should cover only some ten to fifteen base pairs of DNA. That the additional length results from the ability of each operator to bind more than one repressor was shown by Maniatis and Ptashne earlier this year (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 1531; 1973), when they found that upon digesting lambda DNA with nuclease in the presence of

lambda repressor, the size of the protected fragments increases as the ratio of repressor to operator increases. The smallest fragment corresponds to a length of some thirty-five base pairs, the size then increasing with the repressor/operator ratio to 45, 65, 75, 85, 100 base pairs. By comparing the pyrimidine tract sequences obtained from the left operator, they were able to show that each increase in size of the protected fragment represents the addition of a short sequence to the fragment immediately preceding in the series. This suggests a model in which the operator consists of a sequence about thirty base pairs long which binds a dimer of repressor; following binding to this primary site, additional monomers of repressor may add to sequences about fifteen base pairs long adjacent to the primary sequence. A further indication of the complexity of the operator-repressor interaction in lambda is provided by the observation that, although displaying similar hierarchical structures, the left and right operators constitute different sequences—they generate different pyrimidine tracts.

Attempting to define more precisely the structure of the lambda operator, Maniatis and Ptashne have now (page 133) turned to an ingenious exploitation of two restriction endonuclease enzymes which introduce double strand breaks at different sites in the lambda molecule. When lambda DNA is digested with the Hpa enzyme derived from *Haemophilus parainfluenzae*, it is cut in such a way that two fragments are released which contain the operators; a segment of 350 base pairs contains the left operator and a sequence of 2,000 base pairs includes the right operator. Using the second endonuclease, the Hin enzyme of *Haemophilus influenzae*, each of these fragments can be cut into two subfragments. All four subfragments can bind repressor protein, suggesting that each intact operator can be divided into at least two sequences each of which can independently bind repressor *in vitro* in these conditions.

The order of the repressor binding sites within the operator was assigned by taking each of the fragments of length 35–100 base pairs, previously isolated by degrading the repressor-operator complexes formed with different ratios of the two components, and following the effect of the Hin endonuclease. Each fragment was split into two by the Hin enzyme, one subfragment always constituting a length of thirty base pairs, the other corresponding to the remaining length of the particular O_L fragment. What this means is that the primary repressor binding site (that is the fragment of thirty-five base pairs) lies at one end of the operator sequence, the secondary monomer binding sites extending from it in one direction only, comprising about four units of fifteen base pairs each. The action of the Hin enzyme is therefore to separate the primary binding site from whatever secondary sites are attached to it. Similar results are obtained when the right operator fragments are used instead of the left operator—either can be obtained by using mutants of lambda in which one operator lacks affinity for repressor—so that both left and right operators show the same general form of organisation.

By splitting intact lambda DNA with the *Hin* enzyme, Maniatis and Ptashne orientated each operator sequence. They found that the primary binding sequences of thirty base pairs of the left operator can be retrieved in the same fragment as a sequence corresponding to part of the *N* gene; similarly, the corresponding site for the right operator can be reclaimed in a sequence also containing part of the *toF* gene. The primary binding site therefore lies immediately adjacent, or at least very close, to the genes whose expression is prevented by operator-repressor binding; the secondary sites then extend away from the structural genes which are controlled.

Although these results provide a firm basis for some concepts previously held on less sure grounds, they raise several intriguing questions about the precise nature of the lambda operator-repressor interaction. Most notable, of course, is the dramatic difference between the short sequence of the lactose operator and the complex structure in lambda. An important observation, supporting previous speculations, is that the two lambda operators possess different sequences, and as a result have different affinities for the repressor protein, but nevertheless both function to prevent transcription. Also significant is the difference in affinities for repressor of the various sequences included in each operator. Whatever the nature of the DNA sequences which are recognised by the repressor, they can therefore vary in a way which may in future experiments come to throw an important light on the manner of protein-nucleic acid recognition. A puzzling point is the dependence of the secondary sites upon the primary site in the intact lambda DNA molecule; point mutations, apparently located in the primary binding sites, can prevent repression and so allow development of the phage. This means that inactivation of the primary site renders the secondary sites also unable to bind repressor in such a way as to repress transcription.

A final point of speculative interest is the location of the sites on which the restriction enzymes act. The restriction enzymes, of course, are part of the host cell modification and restriction system, which methylates certain sites of DNA native to the cell and also degrades any DNA lacking the appropriate methylations. It is interesting that the sequences recognised by these enzymes should lie so usefully in the control sites of the phage. One possible reason is that restriction and modification activities rely on symmetrical sequences of DNA, as may also the repressor recognition of DNA, providing an obvious resemblance between the two types of sequence. But in teleological terms, it is possible to wonder whether it is only such a coincidence that locates the host modification and restriction sites precisely where they can do most damage to development of the DNA if endonuclease action occurs.

From our Molecular Genetics Correspondent

Defence Mechanisms in Fish

THE capacity of fish to produce antibody on induction with antigen has been known since the early 1900s, and that this production is temperature dependent has been evident since the 1930s. The range of temperature dependence is related to the fish's natural environment, for example, in the warm water carp (*Cyprinus carpio*), antibody can be induced at 20–25° C but not at 12° C, whereas the sablefish (*Anaplopoma fimbria*), from cold waters

in the North Pacific, will produce antibody at 5–8° C. The induction phase of antibody production in fish is prolonged in relation to mammals—18–30 days for cold and temperate species—though some warm water species will produce circulating antibody in less than 9 days. The antibody titres in fish, however, will often equal or exceed the titres obtained in mammals and the circulating antibody can persist for much greater lengths of time—up to one year.

It might be argued that a low temperature which prolongs the induction of antibody will also reduce the virulence of a pathogen, simply by decreasing its metabolic activity. Accordingly, work has been directed to rendering cultured fish immune to various diseases by using the animal's specific immune mechanisms. This work, although still experimental, has met with considerable success though large scale trials on fish farms have generally not been so satisfactory. Nevertheless the fact remains that many fish seem to be severely handicapped and killed by various diseases in a much shorter time than that required for them to produce a measurable immune response, even when they are held in the most favourable conditions yet made available in laboratories. Although some valuable work is being carried out to investigate methods of immunising cultured fish populations (oral vaccination is of necessity the choice because of the large numbers of fish involved), much more ground work is required before applied research can be meaningful; for instance, little is known of the portal by which many important pathogens gain entry into the host fish. It is already known that antibody can be present in localised concentrations according to the site of application of the immunogen, for example, if antigen is administered intravenously the antibody will subsequently be located in the serum, whereas if antigen is fed to the fish in the food, antibody will subsequently be located in the gut mucus. Thus, for protection it would be important that antibody be induced at the site where the pathogen normally enters the host.

Apart from phagocytosis, the non-specific defence mechanisms have not been intensively studied in the lower vertebrates. In this respect the reticuloendothelial system is extensive in the spleen, kidney, heart, liver and gills of many fish species studied. More recent work, however, is providing evidence for the presence of non-specific substances with possible potent protective activity in the tissues and sera of lower vertebrates. The presence of some of these substances seems to be induced, whereas others may be present as normal constituents; for example, the production of an interferon-like substance in fish is elicited by virus and has been shown to confer considerable protection on susceptible cells. Serum titres of lysozyme have been demonstrated to increase (some 100 times) with increase in temperature and immunisation with bacteria, the increase in lysozyme titre being somewhat in advance of antibody production. This finding is contrary to what has been observed in homeotherms. C-reactive protein (CRP) appears in the serum of mammals during injections with microorganisms and has a non-specific precipitating activity. It is now shown by Baldo (see page 145 of this issue of *Nature*) that a substance which seems to have identical activity to human CRP is present in fish serum and will precipitate with extracts prepared from bacteria, fungi and nematodes. Furthermore, it seems likely that this substance is a normal constituent of sera from healthy fish. This could

therefore provide the fish with a potent defence against invading micro-organisms without there being a lag-phase for induction to take place.

An important problem in assessing the results obtained from experiments in fish physiology lies with the technique of husbandry, for the nature and the effect of suboptimal conditions are poorly understood; for instance little is known of the effect of population density, type of diet, handling techniques, nature of water flow and nature of the tank bottom, especially for burrowing species. Husbandry regimes may be stressful and cause a reduction in antibody production on challenge with an antigen, while at the same time increasing stress-induced non-specific substances like interferon and mammalian CRP. Certainly as techniques have improved for maintaining fish in laboratories, many more species have been shown to be immunologically reactive when they were suspected not to be so before, with the notable example of the hagfish, which was until very recently believed to be below the phylogenetic level of adaptive immune capacity.

The prospects for immunological studies in the lower vertebrates are exciting especially with the interest today in the evolutionary and phylogenetic aspects of immunology. Zoologists and medical immunologists are cooperating and the knowledge gained from the evolutionarily simpler systems may well have considerable influence on the understanding of the more complex mammalian counterpart.

FOETAL ABNORMALITIES

Detection of Defects

from a Correspondent

SINCE many countries have relaxed their abortion laws there was a great deal of interest at the Fourth International Conference on Birth Defects (held under the auspices of the National Foundation March of Dimes in Vienna from September 2-9) in methods for the early prenatal detection of birth defects.

J. W. Littlefield (Massachusetts General Hospital, Boston) and C. Valenti (State University of New York, Brooklyn) emphasised the value of early amniocentesis in suitable pregnancies, especially for the detection of foetal chromosomal anomalies and to a much smaller extent biochemical errors. The apparent safety of early amniocentesis was shown by the results of a questionnaire survey carried out in the United

States; in more than 1,600 amniocenteses only ten errors of diagnosis were reported and the maternal and foetal morbidity attributed to this technique was almost nil. Spontaneous abortions following amniocentesis were less common than would be expected for this stage of pregnancy.

Some means for obtaining samples of foetal skin or blood are needed if many more biochemical errors are to be diagnosed *in utero*. This applies particularly to the common haemoglobinopathies. The use of the fibre optic foetoscope would be of great value in allowing samples to be obtained under direct vision, but J. B. Scrimgeour (University of Edinburgh) made it clear that the difficulties (and hazards) of foetoscopy hardly justify the routine use of this technique. By contrast S. Campbell (Queen Charlotte's Maternity Hospital, London) was very optimistic about the expanding use of ultrasound detection of foetal abnormalities (although the foetus is rarely still *in utero*, making it difficult to get a good picture), believing that it will be possible to diagnose some cases of spina bifida, congenital heart and renal disease as well as to measure foetal urinary output by successive measurements of bladder size. The value of serial measurements of biparietal diameter in detecting low growth potential as an indicator of, for example, chromosomal abnormalities was stressed. Ultrasound is non-invasive and has no known hazards at the intensity and pulse length used. D. J. H. Brock (Western General Hospital, Edinburgh) discussed his empirical but pragmatically crucial discovery that amniotic alpha foeto-protein levels are increased in conceptuses with neural tube defects.

Population screening and subsequent counselling aiming to prevent marriage between carriers of the same genetic disease may prove irresistible to public health authorities seeking a sequel to the successful control of epidemic infectious disease. But the experiences of G. Stamatoiyannopoulos (University of Washington, Seattle) should prove a deterrent to excessive zeal, as even a well planned programme involving the sickle cell trait in Greece resulted in the stigmatisation of families following the collapse of marriage plans and the false belief among carriers that they were diseased and it achieved little or nothing in the way of actually reducing the number of heterozygotes marrying.

Mandatory screening, such as has apparently been imposed by some of the States in the United States on blacks, is to be condemned. By contrast M. M. Kaback (Harbor General Hospital, Torrance, California) described the successful screening programme for detecting carriers of Tay-Sachs disease among Ashkenazi Jews in the United States by

ASTRONOMY

Comet Kohoutek

This photograph of Comet Kohoutek was taken by the Royal Greenwich Observatory, Herstmonceux, at 05.00 h on Tuesday (November 6) using a 6-inch diameter lens at $f/4.5$, exposed for 8 minutes on a Kodak II a-O plate. The comet is clearly distinguished from the surrounding stars by its fuzzy appearance, and in particular by its tail, which extends away from the Sun. The scale of the photograph is indicated by the line which represents the radius of the full Moon. When the photograph was taken the comet was 182 million miles from the Earth.

The speed of the comet relative to the Sun was 22 miles per second, so that, during the 8 minutes' duration of the exposure, the comet moved more than 10,000 miles closer to Earth. Recent forecasts suggest that, at its brightest, the comet will be about as bright as the brightest star, Sirius. It may therefore not be bright enough to see in daylight, but should be easily visible in the twilight sky.

finding reduced levels of heat labile hexosaminidase A in serum and leukocytes. Where both husband and wife were deficient, antenatal diagnosis was carried out (in five pregnancies so far) and one foetus was found to have no heat labile hexosaminidase A activity, and was aborted. The success of the Tay-Sachs programme can be attributed to the education level of American Jews and to the availability of an effective means for antenatal diagnosis and induced abortion when necessary. The general value of genetic counselling was upheld by C. O. Carter (MRC Institute of Child Health, London) provided that it is non-directive and follows the initiative of patients rather than doctors.

J. Edwards (Birmingham Maternity Hospital) stressed the non-eugenic nature of genetic counselling conceding its value in assisting individual families.

Genetic engineering was discussed widely. P. A. Marks (Columbia University) described the use of avian myeloblastic virus reverse transcriptase in the production from natural mRNA of DNA coding for alpha and beta globin chains. The major portion of globin structural genes were synthesised and could in turn be used in heterologous cell free systems or intact oocytes to synthesise the appropriate globins. C. Merrill (National Institute of Mental Health, Bethesda) described possible means of introducing new genetic material into intact cells using the examples of prokaryotic genetic exchange. In a workshop on "Advances of Treatment of Hereditary Metabolic Disease" A. G. Bearn (New York Hospital, Cornell Medical Center) reviewed the use of organ transplantation, particularly the apparently successful use of renal allotransplantation in Fabry's disease, but was quite properly cautious about advocating liver transplants in Wilson's disease treatable by less heroic methods.

Of particular interest was the suggestion by P. E. Polani (Guy's Hospital, London) that mucopolysaccharidosis might be controlled by small skin grafts. H. W. Rudiger (University of Hamburg) described the 'Hunter corrective factor' and discussed how it might be produced from urine for therapeutic purposes. It is curious that earlier pyrogenic samples were most efficient in inducing mucopolysacchariduria.

R. G. Edwards (University of Cambridge) reviewed advances in reproductive biology and their implications and discussed the partial success achieved in the selection of X or Y bearing spermatozoa and *in vitro* fertilisation of human ova. There is no doubt that meiotic and early post-fertilisation studies would greatly assist in explaining non-disjunction and polyploidy. It is astonishing how much interference morulae and blastocysts will tolerate and still (in the mouse) develop into a normal foetus. It had proved possible to disaggregate and mix cell lines for study and to cut embryos in half using one half for study and the other half after implantation develops normally. The rarity with which malformed foetuses resulted from the implantation of animal ova fertilised *in vitro* will no doubt encourage those who would do the same in humans.

The moral and ethical issues in biomedical research were brilliantly reviewed by A. G. Mutoulsky (University of Washington) who avoided most of the clichés in considering the implications of the present rapid expansion of technology.

POPULATION ECOLOGY

Hare-Eats-Lynx Effect

from our Animal Ecology Correspondent

MOST biologists are familiar with the concept of population cycles and in particular with the well known and often quoted Canadian lynx-snowshoe hare interaction (MacLulich, *Univ. Toronto, Stud. Biol. Ser. No. 43*; 1937, *inter alia*). The provisions of the Lotka-Volterra equations, developed to describe the dynamics of predator-prey interactions, dictate that peaks of predator density must, temporarily, succeed peaks of prey density. When this dynamic arrangement is depicted according to Rosenzweig and MacArthur's graphical predation theory (*Amer. Nat.*, 97, 209; 1963), with the numbers of predator on the ordinate and numbers of prey on the abscissa, the representation of one complete cycle of interaction is a quasi-circular figure progressing in a clockwise direction (see figure).

It comes as a considerable surprise to read the results of Gilpin's subjection of MacLulich's data to Rosenzweig and MacArthur's graphical analysis (*Amer. Nat.*, 107, 727; 1973). He reveals that, for the 30 years 1875-1906 at least, the figure follows an anti-clockwise direction. This presents a severe interpretational problem because hares simply do not eat lynx. Other 10-year interactions, however, had the expected phase relationship. Gilpin and his colleagues (*Theoretical Population Biology*, in the press) have developed a predator-prey model in which growth rates of low density single species, interspecies coupling constants, intraspecific social interactions and intraspecific interference are considered. This model is much more flexible than the Lotka-Volterra one since it assumes that intraspecific factors are important. When the 30-year lynx-hare data in question were examined by this model the regression fit was poor. So poor that the signs of interspecies coupling constants were reversed. The model reinforced the findings of the graphical analysis that the hare was the predator. How, then,

can the anti-clockwise figure be explained?

Gilpin argues that hares could "kill" lynx if, for example, they carried a disease to them. He investigated the possibilities of this by writing an "epidemic" into his model which took effect only when a certain threshold density of hares had been reached. The "disease" was non-fatal to hares but took its toll of lynx. The results of the "epidemic" on the interaction when expressed graphically closely resembled the plot of the interaction during the 30 unexplained years. This explanation seems to be plausible but for the fact that no such disease has been found to occur in reality. Epidemic disease fatal to hares but not to lynx has, however, been identified (Chitty, *J. Anim. Ecol.*, 17, 39; 1948).

The uniqueness of the series of data on the lynx-hare interaction lies in the number of years over which it was collected. Methodically logged by the Moravian Mission in Ungava since early in the last century, the figures for both species are the number of those trapped, skinned and put up for sale. Perhaps Gilpin has hit the nail on the head when he considers that fur trappers themselves are that elusive "disease". During lean years they turn their attention to chores other than trapping and head for the trap lines only when hares are again abundant. If, once at the lines, they turn a disproportionately large amount of their time to lynx trapping (which is infinitely more profitable and therefore reasonable to assume), they would return bags not inconsistent with the data that produce the curious hare-eats-lynx effect.

MacLulich's classic data may constitute the largest series of its kind on record but, as an indicative statement of actual population densities, their validity may be seen by this model to be in doubt. The model may yet be found to be of widespread ecological use, but the test of it will be as good as the test data.

AIR POLLUTION

Ozone and Wild Plants

from our Plant Ecology Correspondent

MOST of the concern surrounding air pollution in western Europe has centred on sulphur dioxide. In North America ozone has long been recognised as an important phytotoxic pollutant produced in the lower atmosphere by photochemical oxidation of certain products of combustion, especially nitrogen dioxide. The production of ozone is therefore particularly prevalent in urban environments where fossil fuels are combusted in large quantities, especially by automobile engines. Nitrogen dioxide formed in this process is split by ultra-

violet light to nitric oxide and atomic oxygen. The latter combines with molecular oxygen to form ozone. In the Los Angeles basin of Southern California daily peaks of ozone concentration of 15 to 38 p.p.h.m. (parts per hundred million) are frequent in summer and autumn. Even the remote areas of North America often have background concentrations of about 2 p.p.h.m.

Although it is known that ozone is phytotoxic, the threshold concentrations at which toxicity becomes apparent are known for relatively few species. Symptoms of external injury include chlorotic and necrotic lesions, but long before these appear a variety of metabolic processes, including photosynthesis, mitochondrial activity and amino acid synthesis, are affected, as well as membrane permeability. The critical exposures which cause such damage have been examined for some crop and tree species, but little is known of the response of natural plant communities.

Treshow and Stewart (*Biol. Conserv.*, 5, 209; 1973) now have data on the threshold levels of ozone resulting in injury symptoms for a variety of wild plant species. The plants were enclosed in portable fumigation chambers in the field within grassland and woodland habitats in Utah and were exposed to ozone concentrations of 15, 25, 30 or 40 p.p.h.m. for 2 h; they were examined immediately after the experiment and again 2 days later. The experiments were thus concerned with short term, acute ozone pollution rather than long term chronic effects.

Of the seventy species examined, several, including *Bromus tectorum* and *Populus tremuloides*, both important or even dominant species in some types of grassland and woodland in the area, showed visible symptoms of injury after just 2 h exposure at 15 p.p.h.m. ozone. Only five species showed no signs of injury after 2 h exposure to 40 p.p.h.m. ozone. This range and order of sensitivity to ozone agrees well with data already published on crop plants.

Ambient ozone concentrations were generally lower than 15 p.p.h.m. In clearings a level of 9 p.p.h.m. was occasionally reached, but beneath the tree canopy in woodland, values were often less than 1 p.p.h.m. This does not necessarily mean that vegetation was unaffected, since damage at a physiological level normally precedes morphological damage and occurs at lower levels than chlorosis and necrosis. It is also possible that reproduction and germination might be impaired by chronic, low level pollution, which would result in long term changes in the composition of the vegetation.

Treshow and Stewart consider it possible that in time sensitive species may be eliminated, leaving unoccupied

niches and bare ground, which would result in a loss of stability in the vegetation. This is an unlikely event since there are several very resistant species in the communities, including some woody perennials (for example, *Acer grandidentatum*). Changes in vegetational composition could, however, have other repercussions such as the reduction of the productivity of an ecosystem.

BURROWING ANIMALS

Airing the Prairie Dog

from our Animal Behaviour Correspondent
PRAIRIE dogs (*Cynomys ludovicianus*) have a problem. These rodents live in long narrow burrows (about 12 cm wide and up to 30 m long) which must somehow be ventilated. Vogel, Ellington and Kilgore (*J. comp. Physiol.*, 85, 1; 1973) have calculated that, at the very least, there must be complete exchange of the air in the burrow with the atmosphere every 10 h and probably more often. They found that neither diffusion of oxygen through the soil or at the burrow entrance nor the direct action of the wind adequately explains how gas is exchanged with the atmosphere to meet the respiratory needs of the animal. How then do the prairie dogs avoid suffocation?

Vogel *et al.* argue that two physical principles may underlie the ventilation. One is Bernoulli's principle in which

flow is related to pressure differences generated by variations in velocity along a streamline. The other is 'viscous sucking', the attraction of stagnant fluid to adjacent rapidly moving fluid. Either mechanism demands that the two entrances to a burrow be dissimilar. Now it has been known for some time that prairie dogs do indeed build two sorts of entrance to their burrows: 'dome craters' (wide and rounded) and 'rim craters' (narrow, steep-walled, with a rim). But the functional significance of these two types was unknown.

Investigations showed that the typical burrow in a prairie dog town has a rim crater at one end and a dome crater at the other. By dropping smoke candles down some burrows, it could also be shown that when even a slight breeze blew, air entered the burrow through the lower mound and left it through the higher one and that the air in the burrow was completely changed in less than 10 min. They then made scale models of prairie dog burrows in which the height and shape of the mounds at each end could be altered, and found that adequate ventilation would result if the mounds at each end of the tunnel were different either in shape or in height. Real mounds are different in both height and shape, which enhances their effectiveness. The authors point out that this ventilation is efficient almost regardless of which direction the wind is coming from and works even when there is very little wind at all.

Positive Control of Enzyme Synthesis

THE appearance of three articles on the control of repression of the tryptophan operon (*Nature new Biol.*, 245, 131, 133 and 137; 1973) leaves no doubt that negative control of enzyme synthesis exists. More recently (see *Nature*, 245, 407; 1973), it was suggested that positive control for biosynthetic schemes must also exist, and indeed that is precisely what Levinthal, Williams, Levinthal and Umbarger put forward in *Nature New Biology* next Wednesday (November 21).

Levinthal *et al.* have isolated a mutant in *Escherichia coli* K12 that renders the cells sensitive to leucine. The system being examined is the biosynthesis of isoleucine, valine and leucine, so it is no surprise that the enzyme threonine deaminase (specified by the *ilvA* gene) is involved (see *Nature new Biol.*, 244, 34; 1973). Moreover, the *leu^s* mutation has been located within the *ilvA* gene, and it has been found to affect the regulatory properties of threonine deaminase with no concomitant alteration in its catalytic activity.

This unique class of *ilvA* mutant (note that *ilvA* encodes the enzyme threonine deaminase, the first enzyme in isoleucine biosynthesis, and is feedback-inhibited

by isoleucine) affords the putative regulatory role of threonine deaminase to be separated from its catalytic function in isoleucine and valine biosynthesis. The regulatory role not only involves the *ilvADE* operon and the genes *ilvB* and *ilvC* but also, predictably, is involved in the control of the amino acyl tRNA synthetases for isoleucine, valine and leucine.

Earlier Hatfield and Burns (*Proc. natn. Acad. Sci. U.S.A.*, 66, 1027; 1970) had proffered a model to explain such regulatory properties inherent in threonine deaminase; they provided genetic and physiological evidence for the role of the enzyme in regulation of the pathway (at the level of synthesis). They suggested, however, that negative control may apply. Next Wednesday's paper by Levinthal *et al.* indeed confirms their idea that the *ilvA* gene product, strategically located, is a key regulatory target in the cell.

The *leu^s* mutant is found to be recessive to the wild type allele. This indicates the absence of function in the *ilvA* mutant and thus allows Levinthal *et al.* to aver that the wild type gene (*ilvA⁺*) produces a positive effector for the control of enzyme synthesis.

GRAVITATION

Radiation and Collapse

from a Correspondent

SYMPOSIUM 64 of the Extraordinary General Assembly of the International Astronomical Union, held in Warsaw on September 5–8 to commemorate the 400th anniversary of Nicholas Copernicus, reflected the growing interest in general relativity among astronomers and astrophysicists. Entitled "Gravitational Radiation and Gravitational Collapse" the programme ranged over most of the areas where it is believed that general relativistic effects are or soon will be susceptible of observation.

Pre-eminent among these areas is the question of the claims of J. Weber (University of Maryland) to have observed gravitational radiation. His colleague C. Misner reviewed the largely unsuccessful attempts of theoreticians to create models of the copious sources of gravitational waves required by Weber's claims. A short report by A. Poveda (University of Mexico) of a new (remarkably low) upper limit to the rate at which the Galaxy is losing mass of 1 solar mass per year, deduced from the orbits of globular clusters, will not make this task any easier. A. Tyson (Bell Laboratories) followed with an account of the current observational situation in which several groups have sought to repeat Weber's experiments with detectors which are claimed to be of equal or better sensitivity than Weber's 1969–70 antennae and have been unsuccessful.

An afternoon session was devoted to a discussion of these results between the parties involved. In particular R. Drever (University of Glasgow), P. Kafka (Max Planck Institute, Munich) and Tyson presented results which indicate that either Weber has not been seeing gravitational waves or that the source has weakened since 1970. On the other hand Weber made renewed claims concerning coincidences both between his own antennae and between his and those of D. Douglas (University of Rochester). The latter, which amount to some fifty-four zero delay coincidences above random in 7 days worth of data, represent an effect at the 2.7 standard deviation level. The fact that Douglas's instrument operates at 710 Hz would indicate that if this effect is real the signals really are broad band, as has long been suspected. It is hoped that the resolution of the puzzle will be brought about by further plans to exchange tapes and subject the raw data to a variety of signal processes, each favoured by one or other experimental groups. Of future plans perhaps the most striking was V. Braginsky's (State University of Moscow) idea of using a massive monocrystal instead of an aluminium bar with a resultant very

high quality factor to look for the sort of signals astronomers expect from nearby galaxies or gravitational bremsstrahlung produced by close encounters of stars—an idea emphasised by Ya. Zeldovich (Institute of Applied Mathematics, Moscow). Some encouraging progress was also reported on the supercooled detectors.

In the light of this it was amusing to hear J. Faulkner (Lick Observatory, California) suggesting that the effects of gravitational radiation might be found on our own doorstep, so to speak, in that mass transfer taking place in very short period binary star systems seems to be controlled in part by the radiation of angular momentum by gravitational waves.

Rather more positive were the sessions on collapse and black holes. R. Giacconi (American Science and Engineering) summarised the wealth of data from optical, radio and most importantly X-ray observation indicating that Cyg X-1 and SMC X-1 may possibly contain black holes. R. Kraft (Lick Observatory) was able considerably to strengthen the evidence by obtaining a lower bound to the distance to Cyg X-1 and hence a lower bound of $6 M_{\odot}$ to the mass of the

unseen secondary. There was, of course, much discussion of accretion models for such X-ray sources and this underlined the importance of numerical work by S. Teukolsky and W. Press (California Institute of Technology) on the stability of rotating black holes and although not everybody will agree with A. Starobinsky (Landau Institute, Moscow) that his ingenious analytical results on super-radiant scattering of waves off black holes, thereby increasing the energies of the waves at the expense of the black hole, guarantees that stability, they clearly represent important advances in black hole theory. The larger issue of "naked singularities" and whether a black hole can shed the respectable clothing of its event horizon to reveal the singularities inside in more extreme situations than those envisaged in the perturbation approach of Press, Teukolsky and Starobinsky were taken up by R. Penrose (University of Oxford) who provided a useful new definition of naked singularities and repeated previous warnings that the mathematical evidence against such objects is largely non-existent.

Among other topics discussed was the report by B. Carr (University of Cam-

Markers of CNS Malformation

SPINA bifida and anencephaly, two closely related malformations of the central nervous system (CNS), are comparatively common congenital disorders in the population of the United Kingdom, with a combined incidence of about 4 in every 1,000 births. Anencephalics die at birth, but after surgery, children with spina bifida live for a number of years with a high degree of physical and mental handicap. The policy of radical surgical intervention, which prolongs the lives of grossly incapacitated children and puts an enormous burden on their families, has recently been called in question.

A little over a year ago Brock and his colleagues (*Lancet*, ii, 197, 1252; 1972) reported that concentrations of α foetoprotein (AFP) were higher in the amniotic fluids of pregnancies leading to anencephaly and spina bifida. Their study was retrospective—that is, made on amniotic fluids obtained for other reasons and where the outcome of the pregnancy was already known—but it raised the hope of early diagnosis of these conditions followed by termination of the pregnancy. These hopes have now been realised in prospective studies (Lorber *et al.*, *Lancet*, i, 1187; 1973; Allan *et al.*, *Lancet*, ii, 522; 1973) and it is becoming an aspect of routine medical care to monitor pregnancies at risk for CNS malformations through AFP levels in the amniotic fluid. The report of Macri *et al.* in *Nature New*

Biology next Wednesday (November 21) adds a new dimension to these studies in that they have demonstrated a CSF-specific protein in the amniotic fluid of foetal Lewis rats with incomplete neural tube closures. Similar proteins are known in human CSF and, if they leak into the amniotic fluid, may provide another parameter to add to AFP in the early diagnosis of CNS malformations.

The real problem, however, in the antenatal diagnosis of spina bifida is identifying the at-risk pregnancy. Ascertainment through the previous birth of an affected child will allow detection of only a small number of cases, since more than 90% of such children will be born to mothers who have no relevant medical history to alert the obstetrician. Monitoring all pregnancies through early amniocentesis and protein analysis is clearly out of the question. A start to the problem has been made by Brock *et al.* (*Lancet*, ii, 923; 1973) who diagnosed an anencephalic pregnancy through AFP levels in the mother's blood. Presumably this foetal protein crossed the placental barrier from the amniotic fluid. The same is likely to occur with spina bifida, because amniotic fluid AFP is every bit as high. But before large-scale monitoring of maternal serum is contemplated it would be as well to have other markers of CNS malformation. The CSF-specific protein described by Macri *et al.* may be just such a protein.

bridge) on primaeval black holes formed very early on in the history of the Universe. It seems that these very small holes will not grow to gargantuan proportions (that is $10^{16} M_{\odot}$) as had been previously suspected by Zeldovich and Novikov. G. Gibbons (University of Cambridge) outlined some possible quantum mechanical effects associated with very small ($\ll 10^{-10}$ cm) holes, first proposed by S. W. Hawking (University of Cambridge) in collaboration with whom both the above pieces of work were carried out. Of special importance is the question of whether they can possess charge.

After this discussion of gravitational collapses it was peculiarly fitting that S. Chandrasekhar (University of Chicago), the man who in a sense started off the subject with the discovery of the upper limit to the mass of a cold degenerate newtonian configuration which bears his name, should have received the highest award of the Polish Academy of Sciences—the Smoluchowski medal—at this conference. It was also characteristic of his breadth of interests that it was for his work on Brownian motion that he received his award.

NUCLEAR PHYSICS

Continuum Shell Model

from our Nuclear Theory Correspondent

UNTIL fairly recently, nuclear structure and nuclear reaction studies developed almost independently, with occasional connections between the two. It was found most convenient to use a harmonic oscillator potential to generate the wave functions for shell model calculations because of its simple and useful analytical properties. These wave functions are indeed good approximations to the real ones, especially for light nuclei. But this potential arises to

an infinite value outside the nucleus, which ensures that the nuclear wave functions soon fall to zero so that the nucleus is prevented from interacting with anything else.

Nuclear reaction studies, on the other hand, have most frequently used one-body potentials like the optical potential to represent the interaction between an incident particle and the nucleus. Such potentials are essentially energy averaged, so that the particular structural characteristics of each nucleus are largely washed out and the potential is almost the same for all nuclei. Thus, paradoxically, nuclear structure theory allowed no reactions, and nuclear reaction theory was almost independent of nuclear structure.

In particular, the shell model calculations, although very sophisticated, could only give the properties of bound states and states that are in reality unstable to particle emission had to be treated as if they did not decay. Reaction calculations, on the other hand, did not include important features of the structure of the interacting nucleus and were then unable to give an adequate account of the increasingly detailed experimental data. This barrier is now being broken down by nuclear structure calculations that include unbound or scattering particles and by nuclear reaction theories that take detailed account of the structure of the interacting nuclei.

A recent example of the former is the continuum shell model calculations of the structure of ^{15}C carried out by Philpott (*Nucl. Phys.*, **A208**, 236; 1973). This is a fully microscopic shell model treatment of the structure of ^{15}C taking account of continuum states as well as bound states and including configuration mixing, finite range and spin-dependent forces and using fully antisymmetrised wave functions. This gives not only the usual shell model states but also a wide range of resonance phenomena, including broad single-particle and narrow many-body resonance in both elastic and inelastic scattering.

To do this the total wave function is expanded as a sum of states, some localised and some describing the separation of a nucleon from the nucleus. If this is inserted into the Schrodinger equation the usual separation procedure gives a set of coupled differential equations for the bound and unbound wave functions, and these can be solved subject to the appropriate boundary conditions.

These equations include matrix elements depending on potentials that have to be specified explicitly before they can be evaluated. These potentials have one-body and two-body components. The one-body component represents the interaction between each active nucleon and the core, and is

tion and discussion. Part of the problem is that the shorter the event the smaller is the chance of detecting it, especially in continental igneous rocks whose sequences are not continuous in time; and even if an event is found to be recorded in more than one lava flow the relevant outcrops are likely to be stratigraphically unrelated. When to these difficulties is added the fact that the errors on potassium-argon ages are usually comparable to the duration of the events being measured, it is easy to see that events will be difficult to resolve. Nor are deep sea sediments likely to provide the final solution, because, as Watkins (*Bull. Geol. Soc. Am.*, **83**, 551; 1972) has pointed out, although sediments frequently form continuous time sequences, the magnetic data from them are not always too consistent and accurate dating methods are even less applicable than to igneous rocks.

The confusion likely to result is well illustrated by the polarity events within the Matuyama reversed epoch from 2.41 to 0.69 million years ago. One of the major normal events is undoubtedly the Olduvai event which was discovered in rocks from the Olduvai Gorge, Tanzania, and later also recognised in lavas from Alaska and the Cocos Islands as well as in deep sea sedimentary cores. The age assigned to the Olduvai normal basalts by Grommé and Hay (*Nature*,

200, 560; 1963) was 1.92 m.y., and so when Chamalaun and McDougall (*Nature*, **210**, 1212; 1966) found normal polarity lavas of ages 2.03 ± 0.05 m.y. (at the normal to reversed boundary) on Réunion island they tentatively correlated them with the Olduvai event while recognising that there was a significant age difference. Later, however, McDougall and Wensink (*Earth planet. Sci. Lett.*, **1**, 232; 1966) discovered another major normal polarity event (the so-called Gilsa event) at 1.6 m.y. in Icelandic lavas; and this was subsequently also recognised in Tenerife, Alaska and Madeira. Moreover, even more recently, Grommé and Hay (*Earth planet. Sci. Lett.*, **10**, 179; 1971) have revised the age of the Olduvai event to 1.72 m.y.

It now seems probable that the Olduvai and Gilsa events are identical, although the identity cannot yet be considered proved. But what is more certain is that the now-named Réunion event first recognised by Chamalaun and McDougall is quite distinct from both the Olduvai and Gilsa events. At the same time, however, the limits of the Réunion event have never been precisely defined; and so to remedy this deficiency, McDougall and Watkins (*Earth planet. Sci. Lett.*, **19**, 443; 1973) have returned to Réunion to study two sequences of olivine basalt lava flows which between them cover the full reversed-normal-

reversed polarity sequence defining the event.

The stratigraphically higher of the two lava sequences was sampled by the two lava sequences was sampled by four reversed flows overlying two normal flows and separated by a flow whose four specimens gave scattered directions of magnetisation. Since this stratigraphically intermediate flow produced fresh specimens petrographically similar to those from the flows immediately above and below, it seems likely that it was extruded during the normal to reverse polarity transition. The stratigraphically lower of the two lava sequences comprised sixteen reversed flows overlain by eleven normal flows, the whole being overlain by a flow of transitional polarity. The two lava sequences may thus even overlap slightly; but, be that as it may, they certainly record the full Réunion event.

From three potassium-argon dated flows in the upper sequence, McDougall and Watkins conclude that the normal to reverse transition defining the end of the Réunion event took less than 30,000 yr and that the absolute age of the transition is 2.02 ± 0.2 m.y. Similarly, from eight dated flows in the lower lava sequence, they estimate the reverse to normal polarity change at the start of the event to have occurred 2.01 ± 0.01 m.y. ago. Clearly, the lack of a significant age difference between the two transitions means that the Réunion event was very short, probably between 10,000 and 50,000 yr long. This shortness probably explains why the event has been recorded so rarely in deep sea cores, and in this, as well as in absolute age, it contrasts strongly with the much longer Olduvai event.

Finally, there has been some suggestion in the past that there may, in fact, be two distinct normal events around 2.0 m.y. ago. Normal polarity lavas in Alaska, for example, have been dated at 1.95 ± 0.10 and 1.96 ± 0.04 m.y., in Argentina at 2.05 ± 0.02 and 2.06 ± 0.03 , and on Cocos Island at 2.09 ± 0.04 . Insofar as all the errors involved here give ranges overlapping, or almost overlapping, the age range of the Réunion event, the corresponding rocks could represent the same event. Similarly the age of the Réunion event as determined by McDougall and Watkins corresponds closely to the age of 1.99 ± 0.06 or 1.97 m.y. for the W anomaly recognised in oceanic ridge magnetic profiles by Emilia and Heinrichs (*Mar. geophys. Res.*, **1**, 436; 1972). On the other hand, anomaly X, identified by Heirtzler *et al.* (*J. geophys. Res.*, **72**, 2603; 1957), has been dated at 2.3 ± 0.1 m.y. As McDougall and Watkins note, their results neither confirm nor refute the idea of a normal event pair; but data already in existence suggest that the polarity-time scale story is still far from complete.

CHEMISTRY

Dimeric Oxygen

from our Chemical Physics Correspondent
SINCE the ground state of an oxygen molecule contains two unpaired electrons, there has for many years been speculation as to whether the dimer, $(O_2)_2$, could form. In 1924 G. N. Lewis suggested, on the basis of measurements on the magnetic susceptibility of the liquid, that some dimerisation does occur, but most of the recent evidence does not support the presence of abnormal forces between two oxygen molecules. Now, from their spectroscopic studies on the cold gas, Long and Ewing (*J. chem. Phys.*, **58**, 4824; 1973) find clear evidence of dimer formation. Nevertheless they note that such dimerisation is of the type to be expected from a typical van der Waals attraction and does not seem to have any exceptional features associated with the unpaired electrons.

Because of its symmetry an isolated oxygen molecule shows no infrared absorption, although at high pressures some very broad features are observed and interpreted in terms of a loss of symmetry during a collision. The collisions are of short duration, so that the uncertainty principle predicts the ob-

served broadness. The new observation of weak, but much narrower, features on top of the band must indicate a longer lived complex. The most prominent features are at 1,553.3 and 1,557.9 cm^{-1} which is the correct position for the excitation of an O-O stretching vibration. The intensity is proportional to the square of the pressure, which indicates a dimer, and although the features are plain at 87 K they disappear above 100 K. Accurate temperature and intensity measurements indicate a molar energy of formation of -2.3 kJ mol^{-1} . The fine structure of eight lines in all has been qualitatively assigned to changes in the relative rotational motions of the molecules with a low hindering potential.

The electronic absorption centred at 17,282 cm^{-1} also has sharp features superimposed on its collision-induced broad line. These confirm the general picture and a fine structure analysis suggests a vibrational interval of 24 cm^{-1} in the ground state for the mode associated with the intermolecular distance coordinate. The value falls to 18 cm^{-1} in the electronically excited level and both are appropriate values for the weak minimum associated with ordinary van der Waals type intermolecular potentials.

Evolution of Insect Wings and Flight

V. B. WIGGLESWORTH

Department of Zoology, University of Cambridge

Disputes during the nineteenth century as to whether insect wings originated from gills or from paranotal lobes ended with almost universal acceptance of the paranotal theory. Sir Vincent Wigglesworth, however, here gives evidence that the thoracic styli were perhaps the precursors of insect wings, and describes a theory of the origin of insect flight.

THE earliest suggestion for the origin of wings in insects was that of Oken¹ who asserted that in the air-breathing Ancylozoa the external branchial lamellae to which the tracheae ran, hardened and were converted into wings. This view was adopted by Gegenbaur²; but a few years later Müller³ noted that the first instar larva of *Kaloterpes* had prominent expansions from the terga of the pro- and mesothorax, and in later instars from the metathorax. He assumed these to be the rudiments of wings; and since, when they first appeared they were devoid of tracheae, he argued from the principle of recapitulation that they could not have been derived from gills and therefore Gegenbaur must be wrong. Many other ideas are commonly attributed to Müller, but that was all he said.

Disputes over these two theories continued throughout the nineteenth century. The decisive paper seems to have been that of Crampton⁴; a highly judicial work in which twenty-one items of evidence are set out in support of the gill theory and twenty-one items of evidence in support of what Crampton named the paranotal theory. He pronounced judgment unequivocally in favour of the paranotal theory. Snodgrass⁵⁻⁷ in all his writings from 1927-1963 took the same view. At present there is almost universal support for this theory.

Packard⁸ had early suggested that the tergal expansions were first used in gliding, perhaps in a leaping insect. Hinton⁹ started further back and stressed the importance of attitude control of legs and body to ensure that a falling insect landed on its feet and could make a quick getaway from predators, notably spiders. Flower¹⁰, assuming that gliding began in a small insect about 1 cm in length, pointed out that even diminutive paranotal lobes would have been important in attitude control. Then hinges to the planes, and muscular control of their inclination, would lead first to control of the direction of gliding and finally to slow flapping flight¹¹⁻¹⁴.

Gill Theory

In working through the extensive literature I came to feel that the case for the gill theory had been too summarily dismissed. I was impressed by Woodworth's thoughtful paper, which took twenty years in the writing. Woodworth points out that gills are soft, permeable, floppy structures, singularly unsuited for conversion into wings operating in dry air. He argues that it is more likely that the wings should have been formed from some structure accessory to the gills and he

develops a case for the mobile gill plates on the abdomen of mayfly larvae being homologous with wings.

As Heymons¹⁶, Börner¹⁷ and others have shown, the gills of *Ephemera* and *Chloëon* are clearly derived from the segmental appendages of the abdomen. The abdominal appendages of Apterygota are represented by the styli. These are not in fact vestigial legs but the exopodites arising from rounded limb bases or coxites, the main appendages or telopodites of which have been lost. In *Ephemera* the appendages are feathered structures; the intrinsic muscles attached to the base of the styli of Apterygota become the muscles which vibrate the gill lamellae. It is in the free-swimming forms such as *Chloëon*, *Baëtis*, and *Ecdyonurus* that they become most wing-like. They migrate laterally and may even become articulated to the dorsum of the abdomen¹⁸.

The vibrating lamellae are not as a rule themselves the gills: they may be only weakly tracheated; they are often stiffened by veins; the leading margin is often rigid and furnished with hairs and spicules; the posterior margin more flexible. The respiratory component takes the form of tracheated filaments, or simply tracheated areas of the abdominal surface. The gill plates serve to drive currents of water over the respiratory surfaces, and may occasionally be used in locomotion.

In the bottom-living larva of *Caenis* the functional gills are limited to the dorsum of segments three to six of the abdomen. As Eastham¹⁹ showed they set up transverse currents across the abdomen. On the second segment gills are wanting, but there is a pair of remarkably wing-like articulated gill-plates (called 'pseudoelytra' by Eastham) which extend backwards to form a gill chamber for the functional gills. In other mayfly larvae similar gill chambers are formed by the backward extension of the wing lobes. Some mayfly larvae have gill filaments arising below the head and thorax²⁰, but wing-like gill-plates are confined to the abdomen. The *Caenis* larva has a little tapering structure, like an unchanged stylus, projecting laterally below the wing lobe; but this is in fact the vestige of the gill belonging to the first abdominal segment and it is articulated to the postero-lateral angle of that segment.

It is surprising that vibratile gill-plates in mayfly larvae should be confined to the abdomen. One would have expected them to be well developed on the thorax, which is the chief locomotor centre with major ganglia and extensive muscles. That is where the gills are always best developed in Crustacea, as in Euphausiidae. The explanation, of course, is that the thorax is already committed to the development of wings. Börner¹⁷ showed that the gill-plates of *Chloëon* arise from the modified limb-bases of the abdomen. In the thorax the limb-base has provided the pleural stiffening of the thoracic box which extends up to the attachment of the wing lobe. There are no gill-plates to be seen.

If there is any real relation between the wing-like gill-plates of the abdomen and the wings of the thorax it must be sought in the non-existent ancestors of the pterygote insects. Fossils of these have not yet been found. The best we can do is to look at the Thysanura, which are the nearest relatives we have of the early pterygotes. *Petrobius maritimus*, for example, is something like a living fossil; it clearly missed the boat, and has been sitting around on the rocks by the seashore since Devonian times. In *Petrobius* and other

machilids, most of the abdominal segments have styli; and they have serially homologous styli of the same character on the meso- and metathorax, the segments on which the wings of Pterygota develop. I suggest that the thoracic styli of machilids were the precursors of insect wings.

Thoracic Styli

The styli of the thorax in *Machilis* arise from the base of the coxa. They have played an important part in the arguments of morphologists. It is because of their survival in *Machilis* that the abdominal styli have been identified as the exopodites of serial appendages of which the limb-base remains but the main limb or telopodite has been lost^{5,21}. Exitae and endites of the proximal limb segment of arthropods, from trilobites to insects, have an extraordinary history. They have furnished most of the remarkable tools of the phylum: mandibles and other mouth parts; gills of trilobites and Crustacea; swimming and grasping appendages; gill-plates of Ephemeroptera; styliiform gills of Neuroptera, Megaloptera and Coleoptera; specialised parts of the external genitalia. Their evolutionary potential is comparable with that of the vertebrate limb.

There seems no reason why a primary apterygote, adapting to aquatic life, should not have developed gills as in the abdomen of Ephemeroptera. Such an insect would have suffered no phylogenetic inhibitions about developing gill-plates from the styli of the meso- and metathorax. In the course of this process, if the changes in the abdomen of mayflies are any guide, the gill-plates would have migrated towards the dorsum and the articulated bases would have become approximated to the terga. It is of interest that certain of the symphylids carry styli on the base of the second and third pairs of legs, and these styli can become incorporated into the cuticular wall of the segment²².

Although the pleuron in insects is believed to be derived from the limb-base, there is no sign of the recapitulation of this process during embryonic development. It is therefore unlikely that we should get evidence in this way of the coxal origin of wings. The most we can hope for is to see the point of origin of the wing rudiment. Tower²³ looked carefully into this question. He showed that in *Periplaneta* the epidermal thickenings, which form the wing lobes, arise on the sides of the thorax at exactly the same sites as in Coleoptera and Lepidoptera; "but (he writes) the wings soon migrate dorsally and posteriorly, and when they become external appear as direct backward projections of the tergum". Tower could thus find no support for the paranotal origin of wings.

The rather weak muscles which actuate the abdominal gill-plates of mayfly larvae, which are derived from the muscles of the styli, retain their attachment to the coxal or subcoxal limb-base. Corresponding muscles would doubtless have been retained by thoracic gill-plates (although the thoracic styli of existing Thysanura, like the corresponding styli in Symphyla, do not in fact retain their muscles). Such a muscular supply would explain why the two most important direct flight muscles in primitive insects (such as grasshoppers) have their origin in the coxa and run all the way through the thorax to be inserted into the basal sclerites of the wing.

Börner¹⁷ established the homology between the gill bases and the thoracic subcoxae, and showed that the tracheae supplying the gills correspond with the tracheae of the thoracic legs. It is interesting that his figure shows the single trachea, which supplies the wing lobe of *Chloëon*, arising from the leg trachea as it runs towards the coxa.

It is likely that thoracic gill-plates would have been supplied by more powerful muscles, and would be larger structures, than the abdominal gills of mayflies. Lubbock²⁴, who accepted the branchial origin of wings, did not consider that the branchiae of *Chloëon* are used in swimming; but he

claimed that in earlier forms, thoracic branchiae might well have been used for locomotion under water. As Lubbock pointed out, the chalcid wasp *Polynema natans*, as he himself discovered, rows its way under water by means of its wings. Although he did not for a moment suggest that this had any direct connection with the origin of flight, it did serve to show that the same wings could be used for locomotion in the air and under water.

It surprises me that the hypothesis here advanced, that the thoracic styli of Apterygota were the precursors of insect wings, which seems a rather obvious suggestion, seems never to have been put forward before.

Origin of Flight

Ten years ago I put forward a 'dispersal theory' of the origin of flight²⁵, without considering the morphological origin of wings. I now attempt to re-state that theory with special reference to the hypothesis that winged insects arose from a secondarily aquatic ancestor.

The existence of a vast aerial plankton of insects and other arthropods extending up into the sky for at least 14,000 foot is well established. Most of these are winged forms; but wingless Thysanura, Collembola, young stages of Hemiptera and Orthoptera, larvae of Coleoptera, Lepidoptera and Diptera and vast numbers of wingless ants have been captured at heights up to 5,000 foot²⁶.

In our postulated aquatic insect, stranded by the drying out of its breeding places, the vibratile gills, even if used for locomotion under water, could not be used directly as propellers in the air; but they would be pre-adapted for development by the insect of the necessary skills, to increase its buoyancy and keep afloat. I picture a small aquatic insect, in the range of 0.5–1.5 cm, as in existing Thysanura, with mobile thoracic gill-plates, which would thus learn to fly while passively air-borne; not, of course, by studying aerodynamics, but by trial and error.

Such an insect would have had no difficulty in adapting to the dry atmosphere. Judging by existing aquatic insects, the integument could well have retained its waterproof properties²⁷. Existing mayfly larvae use their spiracles solely for moulting²⁸; they are not functional in respiration on exposure to the air. In Odonata larvae, however, some of the spiracles do remain functional in aerial respiration. That could well have been so in our aquatic prepterygote. The long slender cerci of Thysanura, as Leston²⁹ has pointed out, could have been an asset for flight stability, as indeed, in conjunction with the long forelegs, they are in existing Ephemeroptera.

The dispersal theory fits in well with our knowledge of the ecology of flying insects. The central idea which I put forward in 1963 was stimulated in part by the work of Kennedy³⁰ on locusts, of Johnson³¹ on aphids and on Rainey's description of dispersal in the desert locust, which is carried by converging winds and lands where the rain falls³². More recently, both Leston²⁹ and Rainey³³ have favoured the idea that insect flight originated in an arid climate. The climate during Devonian times would have provided the conditions needed for this evolution. The combined Lower, Middle and Upper Devonian occupied some 65 m.y. We read about evidence of torrential rains, of extensive swamps, of arid conditions and the formation of aeolian sandstones and wind-driven layers of sand between sedimentary deposits.

Mamajev³⁴ considers that the Devonian insects were associated with the vegetation in the swamp forest along the banks of lakes and that they were probably not true terrestrial forms but followed a semi-aquatic or amphibious mode of life. It would be indeed surprising if, in the course of 50 m.y., the early hexapods had failed to colonise the inland waters. These aquatic animals would presumably feed like mayfly larvae today: by scraping up the algae and diatoms which must have abounded on submerged stones and vegetation. It is likely that they built up gigantic populations, like

mayflies, so that enormous mortality could be tolerated by the stranded migrants. As Rainey³³ has emphasised, arid and semi-arid areas are characterised by vigorous thermal up-currents developing regularly by day over heated ground and rising at speeds of several m s^{-1} . Insects would be caught up also in whirlwinds and dust-devils and carried up into rain clouds.

It is well to recall the parallel theory of Romer³⁵ which describes the evolution of terrestrial locomotion in crossopterygian fishes in their efforts to crawl out of one drying pool during the seasonal droughts of the late Devonian, and hobble over land to another pool with water in it. Walking limbs arose, not in an effort to colonise the land, but in order to survive in water. Likewise in the aquatic ancestors of winged insects: it is suggested that wings arose to make possible a return to water.

I claim, therefore, that the dispersal theory of the origin of insect flight, most of the elements of which have been put forward at one time or another during the past hundred years, offers the least strain to the imagination, because, as Southwood³⁶, Rainey³², Johnson³¹ and others have pointed out, most of the processes involved have been seen in operation around us to the present day.

Nitrogen Dioxide Concentrations in the Atmosphere

A. W. BREWER & C. T. McELROY

Department of Physics, University of Toronto, Toronto, Ontario

J. B. KERR

Atmospheric Environment Service, Downsview, Ontario

Nitrogen dioxide and its related compounds react strongly with ozone, usually resulting in the destruction of the ozone, and life seems to be delicately adjusted to the radiation shield which the stratospheric ozone provides. We have found that atmospheric NO₂ occurs in two layers, described here, which have very different properties.

NITROGEN dioxide strongly absorbs visible and near ultra-violet light and for wavelengths between 0.43 μm and 0.45 μm its absorption changes rapidly with wavelength. This permits the measurement of atmospheric NO₂ by measuring its absorption of sunlight, using methods similar to those which have been used for ozone for more than 50 yr (ref. 1). We

have adapted a photon counting spectrophotometer² which was originally designed for ozone measurements for this purpose.

The spectrophotometer measures the intensities at wavelengths $\lambda_1 = 0.4377 \mu\text{m}$, $\lambda_2 = 0.4448 \mu\text{m}$, $\lambda_3 = 0.4500 \mu\text{m}$ with slit widths equivalent to about 0.3 nm. At these wavelengths, and for our slit widths, the solar spectrum is at stationary points and strong differential absorption by NO₂ is achieved. If I_1 is the measured intensity at λ_1 and so on, then after the three intensities have been measured, the function, $F = \log_{10} [I_1/I_2] - 1.46 \log_{10} [I_2/I_3]$, is calculated [$1.46 = (\lambda_2 - \lambda_1)/(\lambda_3 - \lambda_2)$]. This function automatically eliminates all effects for which the absorption at the three wavelengths is linear with wavelength. Ozone absorption is reduced to an extent where it cannot cause interference. Rayleigh scattering, though perhaps not totally removed, is reduced to an unobservable effect. On the other hand, a layer of NO₂ (at STP) 10 μm thick will increase this function by 0.007; which we can measure quite reliably, except when intensities are extremely low. We do not know of anything else with sufficient, non-linear absorp-

Fig. 1 The growth of absorption by NO_2 , as measured by our spectrograph. The light source was a quartz halogen lamp. To reduce association into N_2O_4 the NO_2 was dispersed in air at room temperature and pressure in a column 30 cm long. F is defined in the text. The vertical line gives the range of optical absorption observed. The slope of the line is 7 cm^{-1} .

tion to interfere. If we displace all our wavelengths by a small amount we can reverse the effect of NO_2 on our function F , though the measurements become less sensitive. The effects we observe are then quantitatively reproduced but with reversed sign as would be expected.

With amounts of NO_2 comparable with those observed in the optical paths attained in the atmosphere we have confirmed the exponential growth of absorption, which has been reported by others³, and also we have measured the value for the effective absorption coefficient, which is consistent with published values (Fig. 1).

Following the analogy with ozone measurements, we have made measurements of the three intensities in direct sunlight and also in the light scattered from the clear zenith blue sky. When these are made for changing solar zenith angles and especially during the periods near sunrise or sunset, when the Sun is low or below the horizon, useful information can usually be obtained about the amount and vertical distribution.

Observations from the ground in Southern Ontario near Picton at 44°N , 77°W , in conditions of clear air with a visibility greater than 30 km and with a cloudless sky, give measurements of which Fig. 2a and b are typical. The differences between sunrise and sunset are persistent and during the first half of 1973 the sky curves have not changed to a detectable extent.

Low Level NO_2

At large solar zenith angles the direct Sun curve is separated from the zenith sky curve because of the presence of NO_2 near the ground, which, when the Sun is low, usually has a considerably higher concentration than exists in the upper air. This may be seen as follows: the light from the direct Sun passes obliquely through the lower layers and their optical effect is enhanced in accordance with the secant of the zenith angle. On the other hand the light from the clear zenith sky is scattered downward by air at rather high levels and it passes through the low level NO_2 vertically, the absorption of which does not become increased by obliquity. We usually assume this low level NO_2 is below 2 km. Deep convection may carry it upward into higher layers but on the clear days when we take our measurements this will not usually be the case. So long as it is below 10 km it will not alter the conclusions we reach in this paper regarding stratospheric NO_2 .

We can also measure the low level NO_2 by climbing through

it and observing the direct Sun while we do so. We have only two measurements of this kind. One made at noon with a solar zenith angle of about 27° (Fig. 7) when we observed very little NO_2 in the lowest two or three km, less than we could measure with certainty, and much less than was measured at sunrise and sunset on the same day. The second measurement was made in the late afternoon with a solar zenith angle of 75° . The quantities found were less than we typically find at sunrise or sunset but were measurable in amount. The actual concentrations found, assumed, in the case of the observations made from the ground, to be distributed through the lowest 2 km, are shown against the appropriate layer in Fig. 4.

The amount is quite variable but it is subject to a strong diurnal variation. There is very little when the Sun is high. There is on the average about 50% more at sunrise than at sunset. We have made observations on the direct Moon; they have low accuracy but suggest that night time amounts of NO_2 are similar to those observed at sunrise.

NO_2 in the Upper Atmosphere

The chief interest centres on the NO_2 in the upper atmosphere and in the stratosphere. We had hoped to obtain this information from the shape of the 'zenith sky' curves, particularly from that part obtained during twilight. This technique is in routine use for deducing ozone vertical distributions and the methods used for inverting the curves have been widely discussed⁴.

Fig. 2 a, Clear morning observations, July 23, 1973, Picton, Ontario. $\times$, Observed direct Sun; $\circ$, observed zenith sky. ---, Calculated direct Sun; —, calculated zenith sky; both for the sunrise distribution shown in Fig. 4 and using the F_0 as derived in Fig. 6. b, Clear evening observations, July 23, 1973, Picton, Ontario. $\times$, Observed direct Sun; $\circ$, observed zenith sky. ---, Calculated direct Sun; —, calculated zenith sky, both for the sunset distribution shown in Fig. 4 using the F_0 as derived in Fig. 6.

Unfortunately, there is ambiguity about the vertical distributions of the upper atmosphere NO_2 which would produce the observed zenith sky curves. They would be produced either by NO_2 which was almost wholly above 30 km with very little below, or by a suitable NO_2 density at all levels above a few km which changed only slowly with altitude.

The way the ambiguity arises is as follows: it is well known that in the ozone case, the zenith sky curves show an 'Umkehr' and if a well defined layer of NO_2 existed our zenith sky curves would be expected to turn down as the mean scattering level

enters the NO_2 layer and then turn up again when the Sun is below the horizon and the effect of the sunlight passing through the upper part of the layer becomes important. This latter effect which would not arise on a flat Earth is the so called 'second Umkehr'. We observe no vestige of an Umkehr of any kind. This may be because (a) the mean scattering level never enters the NO_2 layer, which, calculation shows, requires that all the NO_2 be above 30 km or (b) there is no layer; that is to say the NO_2 is approximately uniformly distributed through the atmosphere. We do not know of any other way in which the Umkehr can be avoided.

Fig. 3 Observations from an aircraft (12 km), June 13, 1973, Val'd'or, Quebec. $\circ$, Observed direct Sun sunset; $\times$, observed zenith sky sunset; —, mean direct Sun sunset; ---, mean zenith sky sunset; - · -, mean direct Sun sunrise.

Sunrise and Sunset Observations

To resolve this, measurements similar to those described above were made at a height of 12 km at 48°N , 78°W . Because of the height of the observation, the direct Sun could be observed to zenith angles greater than 90° ; this gives the benefit of greatly amplifying the optical path where it is tangential to the Earth, and enables good local concentration measurements to be made at the flight level and below it. The quality and nature of the observations made from the aircraft may be seen in Fig. 3 which shows the observations made at sunset, together with smooth curves drawn through the points. For the morning measurements only direct Sun measurements are available. They are shown in Fig. 3 with data points omitted for clarity.

Fig. 4 Vertical distribution of NO_2 in the atmosphere at different times of the day, as measured over Southern Ontario in first half of 1973.

The direct Sun measurements give absolute concentrations between 6 km and 12 km valid for the instant when the Sun is at a zenith angle of 90° . The accuracy and dependability of these values seem high. They are shown as points on Fig. 4. These observations exclude the possibility of all the upper atmosphere NO_2 being above 30 km with very little below.

The deduced upper atmosphere distributions at sunrise and sunset are then as shown in Fig. 4. These distributions are consistent with all the dusk and dawn observations whether from the air or from the ground. The upper air distributions are necessarily strongly smoothed and are very uncertain above 45 km. In Fig. 5 we show the same data plotted as mixing ratio rather than as concentrations. Each layer contributes most to the absorption at the period when the Sun rays are tangential to the Earth; therefore the curves effectively relate to the instant of sunrise or sunset.

The noontime NO_2 is difficult to measure. The presence of a diurnal variation excludes the use of the normal method. This would be to plot the value of F against the secant of the solar zenith angle ($\sec \chi$). The points should lie on a straight line, the slope of which would be the change in F for vertical transmission and would give the total NO_2 overhead. For the whole day the relation between F and $\sec \chi$ is not linear as is seen in Fig. 6. But near sunset (or sunrise) $\sec \chi$ changes

Fig. 5 Vertical distribution of NO_2 in the atmosphere at different times of the day, as measured over Southern Ontario in first half of 1973. For comparison data from Ackerman and Muller⁶ (---) and Harries⁷ (· · ·) are shown on the diagram.

rapidly, and if in this period the NO_2 is not changing too fast then the slope of the line will be the NO_2 present at that time; if extrapolated back to $\sec \chi = 0$, the line will give F_0 , which is the value the function would have if the spectrograph were taken outside the atmosphere. We have normalised this to zero. Thus we consistently obtain a suitable value for the slope and the intersection occurs at a value very much lower than the instrument reads at noon. This indicates that the total NO_2 overhead at noon is very much larger than is overhead at dusk or dawn.

We therefore deduce that the upper air NO_2 has a large diurnal cycle with much larger amounts present when the Sun is high than at dusk or dawn.

Observations at Noon

To investigate this further we made an aircraft flight at local noon with a solar zenith angle of 27° . The aircraft climbed to 11 km and readings were taken of the direct Sun as frequently as possible during the climb and descent. The slope of the observed value of F against height gives the local concentrations. The measured values are shown in Fig. 7. The corresponding NO_2 concentrations are shown in Figs 4 and 5.

If we use these values, together with the total NO_2 , which is obtained from a ground reading at noon and our value of F_0 as discussed above, we have a suggested noontime distribution shown by the appropriate lines in Figs 4 and 5.

Fig. 6 Observations on the direct Sun, August 3, 1973, Toronto, Ontario. $\times$, Afternoon and evening; $\circ$, morning. The two straight lines are drawn through the points obtained when the Sun is low. Their slope gives the total NO_2 (low level + upper air) at sunset $= 1.65 \times 10^{-3}$ atm cm, and total NO_2 at dawn $= 1.12 \times 10^{-3}$ atm cm. At $\sec \chi = 0$ both extrapolate to F_0 which value is used throughout this work. The total NO_2 at noon was estimated to be 3.5×10^{-3} atm cm.

It is difficult to give absolute limits to the errors possible in these conclusions. The vertical distributions for sunrise and sunset are calculated by finding an NO_2 distribution which, when used in a single scattering model, predicts zenith sky data which agree with observations. The solid lines of Fig. 2a and b are so calculated. If, in any layer between 10 and 40 km, the concentrations are changed from those shown in Fig. 4 by 50% through a depth of one scale height then the fit of the lines to the points becomes unacceptable to the eye. If there were day to day fluctuations of this amount we would notice it in variations of the observations. Similarly if we have wrongly estimated our F_0 by 0.01, which would give an error of 50% in the high noon total of NO_2 , then the curves would be displaced by this amount and it would again be obvious. Errors as large as this therefore seem unlikely.

The diurnal cycle is thus the opposite of that observed in low level NO_2 and is the reverse of that usually hypothesised to occur in the stratosphere. Perhaps the importance of the presence of ozone is underestimated. In the presence of an

Fig. 7 Direct Sun observations at noon, August 3, 1973. For practical reasons the aircraft flight was from Ottawa climbing to North Bay and descending to Toronto. $\circ$, Observed in ascent; $\times$, observed in descent. Solar zenith angle, 27° .

excess of ozone, as occurs throughout the upper atmosphere, NO_2 reacts with ozone to give NO_3 ($\text{NO}_2 + \text{O}_3 \rightarrow \text{NO}_3 + \text{O}_2$). This reaction, which has been discussed by Johnston⁵, is easy to demonstrate in the laboratory. Ozone and NO_2 will exist together in a glass vessel for days showing the clear blue of NO_3 . We presume that the NO_2 goes to NO_3 by night which is photolysed back into NO_2 by day. NO_3 has optical absorption coefficients (H. Johnston, private communication) which should make its measurement with our apparatus possible. We hope to do so.

Overall Distribution of Atmospheric NO_2

(1) Atmospheric NO_2 occurs in two layers which have very different properties.

(2) Near the ground in relatively unpolluted Canadian air there is a very variable amount of NO_2 of the order of 10^{-3} atm cm. This is present at night. It tends to be larger at dawn than at sunset and is greatly reduced when the Sun is high.

(3) For bright, clear days the total NO_2 overhead in the upper atmosphere does not seem to change very much from day to day, but it has a strong diurnal variation, with a maximum near noon. There is about 0.35×10^{-3} atm cm overhead at sunrise, about 3.0×10^{-3} atm cm when the Sun is high though this measurement is very difficult, and about 0.55×10^{-3} atm cm at sunset.

(4) The concentration of the NO_2 does not change rapidly with height, probably up to 40 km. Expressed as mixing ratio it increases strongly with height probably at least to 40 km. We note that this distribution will result in very heavy downward transport of NO_2 and its associated compounds from the upper stratosphere into the troposphere. Suggested distributions at sunrise, high noon, and sunset are given in Fig. 4.

(5) It seems it would be profitable to look for NO_3 in the atmosphere. We hope to do this.

This work has been supported by grants from the National Research Council and from the Atmospheric Environment Service of Canada. The Director General, Civil Aviation, of

the Canadian Department of Transport, provided us with flight facilities during sunrise and sunset. We thank Mr W. T. Tucker for help, and the pilots and the ground staff of the Flight Services Division, Ministry of Transport, for assistance during the flights.

Structure of the λ Operators

TOM MANIATIS & MARK PTASHNE

Biological Laboratories, Harvard University, Cambridge, Massachusetts 02138

The two regions of λ DNA to which the λ repressor binds (the operators) are shown to consist of multiple, non-identical repressor binding sites. The arrangement of these sites with respect to the adjacent controlled genes has been determined using a restriction endonuclease that cleaves each operator.

The sites on DNA to which repressors bind are called operators. In the DNA of bacteriophage λ , two operators are recognised by the same protein, the λ phage repressor. These operators are separated by about 3,000 base pairs (bp), and they independently regulate transcription of two separate operons. Repressor bound to O_L blocks leftward transcription of gene N , and rightward transcription of gene tof is blocked by repressor bound to O_R (Fig. 1, and for review see ref. 1).

Fig. 1 Schematic representation of the λ operators and adjacent genes. The wavy arrows show the direction of transcription of the repressor-controlled genes N and tof . Two arrows indicate the order of repressor binding from the first sites (s_1 and s_1') to the final sites (s_6 and s_6') in O_L and O_R . The Hin cutting sites in O_L and O_R are indicated along with the number of base pairs within the operators on either side of each Hin cut. The repressor gene is cI .

In this paper we describe certain aspects of the structure of the two λ operators. Our conclusions are summarised in Fig. 1, the essential features of which are as follows. Each operator consists of multiple, non-identical repressor-binding sites. These sites are arrayed in the order shown in the figure: at O_L , repressor first binds to a site (labelled s_1), which is about 30 bp long and is adjacent to N ; subsequent repressor molecules add in linear rightward order to the remaining sites

s_2 – s_6 , each of which is about 15 bp long. At O_R the reverse orientation is found: the site to which repressor first binds (s_1') is at the right terminus, and subsequent repressor molecules bind in linear leftward order. We present here only the essential evidence for these assertions; a more complete description of some of these experiments is found in ref. 2.

The λ operators may be isolated by digesting ^{32}P -labelled λ DNA with DNase in the presence of λ repressor^{3,4}. The protected fragments, bound to repressor, are then trapped on nitrocellulose filters, eluted and examined on polyacrylamide gels. Using the appropriate mutant DNAs it is possible to isolate O_L and O_R separately. We⁴ obtained results of an unanticipated complexity from these nuclease digestion experiments. When the ratio of repressor to operator was increased, six successively larger DNA duplexes were recovered from each operator. The smallest of these was about 35, the largest about 100 bp long, and the intermediate fragments differed in length by about 10 to 15 bp. Analysis of the pyrimidine tracts of these fragments revealed that, at each operator, the site to which repressor first binds is unique (though not necessarily terminal), and that the adjacent sites are then filled sequentially. Within each operator the adjacent sites are not identical repeating sequences and, moreover, the sequences in O_L differ from those in O_R , a finding consistent with the observation that O_L and O_R differ in their affinities for repressor.

Restriction Endonucleases

Our experiments exploit two restriction endonucleases, each of which makes over thirty-five double stranded cuts in λ DNA. One, called Hin , is isolated from *Haemophilus influenzae*, and the other, Hpa , is isolated from *Haemophilus parainfluenzae*. Each is known to be a mixture of more than one restriction enzyme (ref. 5 and Smith, personal communication), but we have found it unnecessary to fractionate these activities. Figure 2 shows the cutting sites of Hpa and Hin in the region of O_L and O_R . The location of these cutting sites was determined in most cases by hybridising the fragments to various deletion and substitution mutants of λ , and in some cases by digesting mutant DNAs and examining the products on polyacrylamide gels². The sizes of the various fragments produced by Hin and/or Hpa , indicated on the figure, were determined as described in ref. 2.

Our restriction endonuclease experiments received their initial impetus from the discovery of Allet⁶ that one of the fragments generated by the action of Hpa on λ DNA is located near the beginning of N , and another includes tof . In collaboration with Allet we found that these fragments, 350 and

Fig. 2 Schematic representation of a portion of the λ genome showing portions of Hpa and Hin cleavage sites in and around O_L and O_R . The approximate numbers of base pairs between the various cutting sites are indicated. The determination of the various cutting sites is described in ref. 2.

2,000 bp long, bind repressor (unpublished), and further experiments confirmed that they contain intact O_L and O_R respectively². Encouraged by this indication that O_L and O_R can be separated, we sought and found another restriction endonuclease that cuts within each operator. As we shall show, this enzyme (Hin) splits the first repressor binding site from the remaining sites in each operator, and Hin fragments containing either the primary or the remaining operator sites bind repressor.

Operator Fragments produced by Hin and Hpa Cutting of Whole λ DNA

When λ DNA is digested with Hpa, two (and only two) fragments are generated which bind repressor. This is shown by the experiment of Fig. 3a. Hpa-digested, ^{32} P-labelled

Fig. 3 Operator-containing fragments generated by digestion of whole λ DNA with Hpa and Hin. Hpa and Hin were isolated and used as described in ref. 2. a, 10 μ g ^{32} P-labelled (1.0×10^6 c.p.m. μ g⁻¹) λ DNA was digested with Hpa for 15 h at 37°C in Hpa buffer². Following phenol extraction, a two-fold excess of λ repressor was added to the digested DNA and the mix passed through a nitrocellulose filter. DNA eluted from the filter^{3,4} was examined by electrophoresis through a 4% polyacrylamide Tris-acetate gel¹². b, 25 μ g (5×10^5 c.p.m. μ g⁻¹) ^{32} P-labelled λ DNA was digested with Hin for 15 h at 37°C in Hin buffer²; thereafter the samples were treated as in a. Chain lengths of the duplexes eluted from filters are indicated on the figure.

λ DNA was mixed with λ repressor, passed through a nitrocellulose filter, and the fragments trapped on the filter by repressor were eluted and examined by gel electrophoresis. Two fragments, 350 and 2,000 bp long, were recovered. (The total digest contained over fifty specific fragments (see Fig. 4b of ref. 2).) As indicated in Fig. 2, Hpa 350 contains an intact O_L and Hpa 2,000 an intact O_R .

Fig. 4 Hin cutting of isolated operators. Operator fragments (O_{LI} , III, IV, V, VI and O_{RV}) were purified as previously described⁴, digested with Hin for 15 h at 37°C in Hin buffer², and subjected to electrophoresis on a 12% polyacrylamide Tris-Borate-Mg²⁺ gel⁴. Columns labelled '-Hin' show operator fragments incubated under the same conditions but without Hin. Chain lengths are indicated on the figure. In every case except one (O_{LI}) the columns labelled '+Hin' contain some undigested operator, indicating that a limit digest was not achieved.

When this experiment was performed with Hin instead of Hpa, we observed a strikingly different result. In this case four fragments were selectively bound to the filter by λ repressor, indicating that Hin cuts within each operator once, generating two repressor-binding fragments from each operator (Fig. 3b). As shown in Fig. 2, two of these Hin fragments (Hin 320 and Hin 1,125) contain portions of O_L , and the other two (Hin 550 and Hin 375) contain portions of O_R . As predicted from these results, two repressor binding fragments are generated by Hin digestion of either operator-containing Hpa fragment (Fig. 5 of ref. 2). An important conclusion from these experiments is that the secondary repressor binding sites specifically bind repressor even when separated from the primary repressor binding sites in each operator. Thus each operator must contain more than one sequence recognised by repressor. A direct confirmation that Hin cuts each operator is presented below.

Hin Cuts Isolated λ Operators

Five operator fragments were purified from O_L by pancreatic nuclease digestion of the appropriate λ mutant DNA in the presence of varying amounts of repressor as described previously⁴. These duplexes, designated O_{LI} , III, IV, V and VI, are 35, 65, 75, 85 and 105 bp long. Each of these fragments was treated with Hin and the products examined by gel electrophoresis (Fig. 4). In each case two fragments were generated; one was about 30 bp long, and the other varied in length depending on the size of the particular O_L fragment. A schematic representation of the results is presented in Fig. 5. Two important conclusions emerge from this result: (1) Hin cuts once in O_L , near the junction between the first (s_1) and second (s_2) binding sites, and (2) s_1 is terminal, and the remaining sites are filled in linear order.

This experiment has also been performed using the 85 bp operator fragment isolated from O_R (O_{RV}). In this case the

same result was observed as with the corresponding $O_L V$ (Fig. 4). From experiments described below we deduce that the 30 bp fragment split from $O_R V$ by *Hin* is s_1 . We conclude therefore that as in O_L , the first repressor binding site in O_R (s_1) is terminal, the sites are filled in linear order, and *Hin* cuts between s_1 and s_2 .

Orientating the Operators

We have argued that one of the many *Hin* cutting sites in λ DNA is within O_L between s_1 and s_2 , and another is within O_R between s_1' and s_2' . This conclusion predicts that of the two O_L -containing *Hin* fragments generated from whole λ DNA, one should contain s_1 , the other s_2-s_6 . Similarly, the two O_R -containing fragments should contain, separately, s_1' and $s_2'-s_6'$. The experiment of Fig. 6 verifies this prediction and, moreover, reveals the important new fact that each operator is orientated such that s_1 and s_1' are proximal to *N* and *toF* respectively. To perform this experiment, the four operator-containing *Hin* fragments, labelled with ^{32}P , were isolated from whole λ DNA as described for the experiment of Fig. 3, digested with pancreatic DNase in the presence of excess repressor, and recovered from nitrocellulose filters. Figure 6 shows that the two *Hin* fragments known to contain *N* and *toF* sequences (*Hin* 320 and *Hin* 550, respectively, see Fig. 2) yielded duplexes 30 bp long, the known sizes of s_1 and s_1' . Larger pieces were protected from the other two *Hin* fragments: the fragment containing the right part of O_L (*Hin* 1,125) and that containing the left part of O_R (*Hin* 375) yielded, respectively, duplexes 75 and 55 bp long which we identify as s_2-s_6 and $s_2'-s_6'$. (The fact that s_6 was not protected in this particular experiment is consistent with our observation that, compared with O_L , more repressor is required to protect the largest fragment of O_R (ref. 4).)

Fig. 5 Schematic representation of the effect of *Hin* on isolated O_L fragments. The vertical arrow labelled *Hin* shows the position of the cutting site within the various operator fragments. The horizontal arrow shows the order of repressor binding sites s_1 to s_6 .

The results of the experiment of Fig. 6, taken in conjunction with the fact that each operator is filled with repressor in linear order, orientates each operator as shown in Fig. 1. s_1 and s_1' are proximal to *N* and *toF* respectively. O_L binds repressor beginning at its left extremity and subsequent repressor molecules are added in a rightward direction, whereas the opposite is true at O_R .

Fig. 6 Operator fragments contained in four *Hin* fragments. The four operator-containing *Hin* fragments were isolated as in Fig. 3b and eluted from the gel. Repressor was added to ten-fold molar excess and the samples digested with DNase^{3,4}. The protected fragments were examined on 12% TBM polyacrylamide gels⁴. Sizes of the protected fragments are indicated on the figure. a, *Hin* 320; b, *Hin* 1,125; c, *Hin* 375; d, *Hin* 550.

Further Results and Discussions

Several additional findings, evidence for which may be found in ref. 2, are as follows: (1) The two *Hin* fragments identified as containing s_1 and s_1' (*Hin* 320 and *Hin* 550) bind repressor more tightly than do the two *Hin* fragments containing s_2-s_6 and $s_2'-s_6'$ (*Hin* 1,125 and *Hin* 375). The order of affinities is *Hin* 320 > *Hin* 550 > *Hin* 1,125 > *Hin* 375. We estimate that, for half-maximal binding, s_2-s_6 requires about three- to five-fold more repressor than does s_1 , and $s_2'-s_6'$ requires about ten- to fifteen-fold more repressor than does s_1' as measured using the various operator-containing *Hin* fragments. (2) An operator constitutive mutation has been located in s_1 . (The repressor affinity of *Hin* 320, but not that of the remaining three operator-containing *Hin* fragments, is reduced (about three- to five-fold) when *Hin* fragments are generated from DNA bearing this mutation.) (3) The distance between the left extremity of s_1 and *N* is less than 20 bp.

The experiments reported here, taken in conjunction with our earlier work², show that each λ operator contains multiple repressor recognition sites. In all, there are at least four and may be as many as twelve different sites specifically recognised by one protein, the λ phage repressor. Although the two λ operators differ in their sequences and affinities for repressor⁴, the arrangement of binding sites with respect to the adjacent controlled genes is the same in the two cases. In both cases the strongest affinity site is adjacent to the controlled gene, and repressor fills the operator linearly in the direction opposite to that of transcription of the structural gene. At least one sequence is common to both operators, namely, the *Hin* cutting site located between the first and second binding sites in each operator.

The λ operators are more complex than the *lac* operator, which consists of a single sequence about 25 bp long⁷. It may be relevant to note that the only molecular species of *lac* repressor known to bind DNA is a stable tetramer of identical subunits of molecular weight 40,000 (refs 8, 9). The λ repressor, in contrast, has the property that its subunit (molecular weight 30,000) is in concentration-dependent equilibrium with dimers and tetramers^{10,11}, and we deduce from the different sizes of the binding sites on λ DNA that more than one form of the λ repressor binds to DNA. Whatever the significance of these observations may be, one principle of DNA-protein interaction that emerges from the study of the λ case is that the presence of multiple, non-identical binding sites enables a small protein to cover a relatively long and unique stretch of native⁴ DNA.

We thank Andrea Jeffrey, Debbie Gernes and Janet Tobey for technical assistance. We are grateful to Bernard Allet for communicating unpublished results, to B. Allet, R. Roberts and J. Sambrook for discussions and to S. Flashman for mutant strains. T. M. was supported by a National Institutes of Health Postdoctoral Fellowship. The work was funded by a grant from the National Science Foundation.

Deuterium Formation Hypothesis for the Diffuse Gamma-ray Excess at 1 MeV

MANY measurements of the diffuse X-ray and γ -ray background¹⁻⁴ indicate that it consists of an inverse power law spectrum with index ~ 2.0 . Spectral features or excesses are reported in the vicinity of ~ 40 keV and ~ 1 MeV. When plotted on linear-linear paper the 1 MeV excess is seen to consist of a pronounced peak in the 0.5 to 2.0 MeV region with a feeble tail extending on to higher energy (Fig. 1). In this paper a simple explanation is presented for the 1 MeV peak in light of new experimental and theoretical advances made in the past year. No explanation is presented for the higher energy excess and it is presumed to come from other mechanisms. I hypothesise that the peak arises from the astrophysical production of deuterium by the two body recombination process ($p+n \rightarrow D+2.2$ MeV γ ray) in an environment transparent to the emitted γ rays. The hypothesis is shown to lead unambiguously to two remarkable numerical results: a calculation of the terrestrial $n(D)/n(H)$ ratio; and a prediction of QSO cutoffs at $z \sim 3$.

The most recent measurement of the γ -ray background made on Apollo 15 has confirmed the 1 MeV feature⁴. Although the large uncertainties associated with this spectrum ($\sim 30\%$) may seriously effect the shape and magnitude of any extracted excess curve, it nevertheless seems reasonable to accept the data at face value and investigate the consequences, bearing in mind that future, more precise data may change the arguments considerably. In Fig. 1 the difference between the Apollo 15 spectrum and an $E^{-2.0}$ extrapolation of the low energy power law portion of the Apollo 15 spectrum is plotted. (The discussion to follow is substantially unaltered by changes in the power of the extrapolation $\lesssim 10\%$.) The Apollo 15 spectrum has been used because it is most recent and spans both the power law and 1 MeV excess regions of the spectrum. Several origins of the feature have already been suggested. These are summarised and discussed in a recent paper by Stecker³. At present none of these has yet been widely accepted. Here I argue generally in support of the position of Clayton and Silk⁵ who suggest that the origin of the feature is in γ -ray lines emitted by heavy radioactive nuclei after their

synthesis in supernova explosions throughout the Universe. But it is suggested in light of recent discoveries that Clayton and Silk⁵ (CS) have not discussed what may be the most important γ -ray line emitted in astrophysical nucleosynthesis, namely the 2.2 MeV deuterium recombination line. The large potential enhancement in γ -ray line signal from this mechanism significantly strengthens the argument for a line origin of the feature.

The unambiguous astronomical detection of deuterium^{6,7} has now removed all doubt concerning its existence on a galactic scale. Some doubt exists concerning its relative abundance, but it is reasonable to assume that the $n(D)/n(H)$ ratio approximates the terrestrial value of $1-2 \times 10^{-4}$ on a galactic scale. In view of this large abundance, Hoyle and Fowler⁸ and Colgate⁹ have argued that the D may be made astrophysically under non-thermodynamic conditions rather

Fig. 1 Plot of the 1 MeV diffuse γ -ray excess above an $E^{-2.0}$ power law extrapolation of the lower energy spectrum. Also shown (---) is a theoretical spectrum based on the deuterium formation hypothesis and cosmological assumption discussed in the text. The energy axis is also labelled in time and distance for the cosmological model used.

than cosmologically. Specifically Hoyle and Fowler suggest that α particles accelerated in a supernova shock wave can produce D and neutrons in the outer envelope by a spallation reaction and the neutrons may subsequently recombine with the ambient hydrogen also to make D. In view of the present rudimentary understanding of the details of supernova explosions, it is difficult to decide whether the direct production of D is more important than the indirect recombination process. Hoyle and Fowler⁸ conclude that the recombination process can be an order of magnitude more efficient if the H gas density is high enough for most of the neutrons to be captured.

Strong evidence in support of the contention that recombination can be an important astrophysical process in an environment which is transparent to 2.2 MeV γ rays was obtained by Chupp *et al.*¹⁰. Observation of two intense solar flares with a satellite borne detector revealed that the dominant feature in the γ -ray spectrum was the 2.2 MeV deuterium recombination line. Ramaty and Lingenfelter¹¹ have shown that the propagation of ~ 10 MeV neutrons in an H atmosphere is determined by elastic and inelastic np scattering with D formation occurring at a range of about 1.6 g cm^{-2} . Since the stopping range of a 2.2 MeV photon is about 25 g cm^{-2} these workers conclude that the solar flare γ rays will escape unattenuated. Although I am not arguing for a solar flare origin of the 1 MeV excess, it is important to see that it is clearly possible to construct astrophysical models which will be compatible with the D hypothesis.

On the basis of a simple abundance argument, $(n(^{56}\text{Fe})/n(\text{H})) = 3.1 \times 10^{-5}$ and the assumption that the ^{56}Fe in the Universe was produced by radioactive decay from supernova produced ^{56}Ni and ^{56}Co , CS concluded that the dominant lines in the 1 MeV excess should be from this process. Their flux estimate indicated that it might be possible to account for most of the excess with these lines. Assuming that recombination is the important D production mechanism on a cosmic scale and noting that the $n(\text{D})/n(\text{H})$ ratio may be an order of magnitude greater, I conclude that D recombination can more easily account for the excess. The subsequent discussion does not depend on a supernova origin of D but only on the pre-eminence of astrophysical D production by recombination and the transparency of the source to 2.2 MeV γ rays. But D formation may take place in the outer envelope of supernova from which the probability of γ -ray detection could be high relative to γ -ray detection of heavy element nucleosynthesis at the core which must await the expansion of the remnant before becoming detectable. Once out of the source, absorption in the interstellar and intergalactic medium is expected to be negligible.

The exact shape of the expected D feature depends on the cosmological model one assumes and also on assumptions concerning the time dependence $f(t)$ of the galactic synthesis rate of D. Clayton and Silk have derived expressions for the shape of the spectral feature anticipated from a single γ -ray line. Clearly one expects an edge at the rest energy of 2.2 MeV and a continuous distribution towards redshifted energies from D synthesised at earlier times in distant galaxies. Eventually at lower energies the distribution will disappear as one looks at the epoch prior to the beginning of astrophysical nucleosynthesis assumed to start at time t_* in all the galaxies.

To show that the observed feature is consistent with reasonable cosmological assumptions a computer constructed plot of the expected shape is given in Fig. 1 for an Einstein-de Sitter universe, $q_0 = 0.5$, $\rho_0 = 5 \times 10^{-30} \text{ g cm}^{-3}$ for which $\gamma = 1.5$. Employing the current value of $55 \text{ km s}^{-1} \text{ Mpc}^{-1}$ for the Hubble constant yields a universe of age $t_0 = 11.9 \times 10^9 \text{ yr}$. The data indicate a rate of nucleosynthesis peaked in the past for which an exponential form $f(t) = f_0 \exp[-\lambda t]$ has been assumed. Following CS, equation (8), a theoretical flux curve of the form

$$F \propto \exp(-\lambda t_0(E/2.2)^{\gamma})(E/2.2)^{\gamma-1} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \text{ MeV}^{-1}$$

amplitude normalised to fit the data at 2.2 MeV has been used.

At this point it is important to point out that t_* , λ , and f_0 are now determined by the data. The low energy edge at E_* determines $t_* \sim 2.1 \times 10^9 \text{ yr}$ through the expression $t_* = t_0(E_*/2.2)^{\gamma}$; the shape of the 1 MeV feature determines $\lambda^{-1} \sim 6.5 \times 10^9 \text{ yr}$; and its amplitude determines f_0 . The quantity f_0 can most easily be determined from a cosmological correspondence principle—for small distances and redshifts the results of relativistic calculations in curved spaces must go over to the results of non-relativistic calculations in Euclidean spaces. So the incremental flux ΔF in the energy interval E to $E + \Delta E$ and the time interval t to $t + \Delta t$ arises from galaxies at distances r to $r + \Delta r$ and is given non-relativistically for small r by

$$\Delta F = (1/4)n_g f_0 \exp(-\lambda t) \Delta r \text{ cm}^{-2} \text{ s}^{-1}$$

where n_g is the average density of galaxies taken to be $1.0 \times 10^{-75} \text{ cm}^{-3}$. The factor $1/4$ arises $(1/2)$ from the fact that γ rays emitted on the far side of a thick synthesising object like a supernova have no chance of reaching us and $(1/2)$ from the angular distribution of galaxies with respect to a flat 1-cm^2 detector. Using the value of λ determined from the shape of the excess and evaluating ΔF for an interval Δr near $r=0$ yields $f_0 \sim 1.2 \times 10^{47} \text{ s}^{-1}$. In the above estimate I have neglected: (1) all other possible contributions to the 1 MeV excess (such as the ^{56}Ni and ^{56}Co γ -ray lines); (2) the possibility that nucleosynthesis did not begin at the same time t_* in all galaxies; (3) any Compton scattering of the γ rays before detection; and (4) the large energy resolution ($\sim 10\%$) of the detectors employed on Apollo 15. The sharp edge predicted by the D hypothesis at 2.2 MeV is only hinted at in the data, presumably because of instrumental smearing and background effects.

If the above discussion is taken seriously and absorption of the γ rays in the source is neglected the $n(\text{D})/n(\text{H})$ ratio can be estimated in the Galaxy for D produced by recombination. The total number of D nuclei, $N(\text{D})$, is given by

$$N(\text{D}) = \int_{t_*}^{t_0} f_0 \exp(-\lambda t) dt = 1.3 \times 10^{64}$$

Taking the Galactic mass to be $1.1 \times 10^{11} M_{\odot}$ containing 70% H by mass yields $N(\text{H}) = 9.2 \times 10^{67}$. Thus a D/H ratio of $\sim 1.5 \times 10^{-4}$ is obtained which is in agreement with the terrestrial value. Moreover this result is relatively insensitive to cosmological models which basically serve to fix the time axis of Fig. 1 and the specific form of $f(t)$, depending primarily on the area under the curve in Fig. 1. But in the light of the many uncertainties in the above estimate the exact agreement with the terrestrial value must be fortuitous, although it nevertheless indicates that the calculation gives an order of magnitude estimate which is correct. I take this remarkable result to be significant evidence for the correctness of the deuterium hypothesis and hope that it will stimulate the search for the astrophysical origin of D. In particular, models of supernova which allow for large scale D production by recombination and the detection of the 2.2 MeV γ rays should be pursued.

Additional support for the D hypothesis comes from the observation of quasar redshifts $z(z \equiv 2.2/E - 1)$. If QSOs are indeed young galaxies and it is assumed that their emission is not occurring before the beginning of D nucleosynthesis at time t_* then Fig. 1 predicts the large z redshift behaviour to be expected. It is apparent that the number of quasars detected at $z \sim 2$ should be falling off rapidly with the distribution disappearing at $z \sim 3$. This agrees with the experimental evidence.

Finally, experimental support for the deuterium hypothesis could come with the detection of a strong 2.2 MeV line from a reasonably local supernova explosion and/or the detection of a 2.2 MeV edge in the diffuse background. For these measurements the application of a high resolution γ -ray telescope is indicated. Detection of large amounts of D in

the vicinity of a supernova remnant by other means would also be supporting evidence.

Average Trace Element Composition of Low Level Marine Atmospheric Particulates

GROWING concern has been expressed^{1,2} over the introduction of pollutant trace metals to the oceans through the atmospheric transport of particulates from the continents. Few data exist on the elemental composition of such particulates, and those available are usually from restricted regions³⁻⁵. We have carried out a sampling programme^{6,7} in which particulates have been collected from seawater and from the lower atmosphere (~15 m above the sea surface) over large tracks of the world ocean. The collection details have been described elsewhere⁶ and the distribution of Pb in Atlantic particulates has been reported⁷. Here we present data on the average trace metal composition of aeolian particulates from the lower atmosphere of various major wind systems over the World Ocean.

Particulates were sampled from the following wind systems (number of samples in parentheses): North Atlantic Westerlies (4); Atlantic Westerlies/North East Trades boundary region (3); Atlantic North East Trades (7); Atlantic ITCZ (3); Atlantic South East Trades (5); variable winds, South African Coast (7); North-east Monsoon, northern Indian Ocean (3); variable winds, southern Indian Ocean (3); South-west Monsoon, South China Sea (9); northerly wind, East China Sea (1); variable winds, Japanese coast (6). The average trace metal composition of each of these dusts is given in Table 1.

The distribution of some trace elements in low level marine aeolian dusts can vary geographically⁷. This is particularly true of those elements which have a significant man-induced (anthropogenic) component because the relative proportion of this component will decrease with distance from a specific source of pollution. As a result, concentration ranges in the dusts can be relatively large. But in particulates which are not obviously associated with known sources of pollution it is difficult to distinguish between a natural and an anthropogenic origin of trace elements unless there are data on the average distribution of such elements in aeolian particulates from the

low level marine atmosphere. The data given in Table 1 will help to provide such an average.

To identify those trace elements which potentially have a significant anthropogenic contribution Goldberg² has employed an 'enrichment factor', based on the ratio of an element to iron in atmospheric particulates, divided by the ratio of the same elements in average crustal material. Similar calculations have been made for the elements in the particulates from the low level marine atmosphere. Since the ultimate source of natural trace elements in atmospheric particulates is crustal material, from which they are released by the action of geological processes, the enrichment factors should be around unity if natural sources predominate. But these trace elements can undergo considerable fractionation during processes such as weathering and degassing, and the enrichment factors can only be regarded as indicating to a first approximation those elements which potentially have a significant contribution from an anthropogenic source. From the results which are given in Table 1 it can be seen that for the elements Mn, Ni, Co, Ga, Cr, V, Ba and Sr the enrichment factors are reasonably close to unity; in other words, these elements are not significantly enriched in average low level marine aeolian particulates, and in fact Co and Sr are depleted, relative to average crustal material. In contrast, the elements Sn, Pb and Zn are enriched in the aeolian particulates, relative to average crustal material, by one order of magnitude even when geographical variations are smoothed out by taking a 'world-wide' average. These factors have been used to identify those elements which are contaminating the atmosphere², and it may be concluded that Sn, Pb and Zn are being released preferentially into the marine atmosphere (from sources which probably include the activities of man) and are concentrating, relative to average crustal material, in low level aeolian particulates.

Table 1 Average Trace Element Composition of Low Level Marine Atmospheric Particulates

Element	Concentration	Enrichment factor *
Fe	5.2 (2.2-9.9)	—
Sr	101 (17-203)	0.35
Co	9 (3-36)	0.45
Cr	85 (21-850)	1.2
V	145 (37-530)	1.4
Ba	487 (57-1,100)	1.4
Mn	1,312 (310-3,720)	1.5
Ni	91 (10-720)	1.5
Ga	21 (5-41)	1.6
Cu	157 (23-490)	3.4
Zn	683 (136-3,100)	13
Sn	30 (1-120)	19
Pb	465 (29-2,750)	49

* See text.

Concentrations are in p.p.m., with the exception of Fe which is given in wt %; the figures in parentheses indicate the ranges found.

We thank the Blue Funnel Line for permission to make collections from their ships; the master, officers and crew of the MV Cyclops; A. J. Woodward for help in the collection of samples; and the Natural Environment Research Council for financial support.

New Radiolarian Palaeoclimatic Index in the Plio-Pleistocene of the Southern Ocean

PLIOCENE-PLEISTOCENE palaeoclimatic investigations in the Southern Ocean have been carried out using five groups of microfossils: foraminifera^{1,2}, calcareous nannofossils³, Radiolaria⁴⁻⁹, diatoms¹⁰, and silicoflagellates¹¹. Radiolarian methods are particularly valuable in higher latitudes where carbonate sediments are susceptible to dissolution even in relatively shallow waters^{12,13}. Established radiolarian techniques are based on oscillations of cold-water (Antarctic) relative to warmer-water radiolarian assemblages, established by determining their distribution in Recent sediments relative to the Antarctic Convergence (Polar Front)⁴. The cold-water assemblage used in these palaeotemperature determinations consists of eight species, whereas the warm-water assemblage consists of nine species^{4,9}. Of the several dozen species known in Southern Ocean Quaternary sediments, these seventeen species represent more than 75% of the individuals⁴.

Here I describe a new radiolarian palaeoclimatic method, based on frequency oscillations of *Antarctissa strelkovi* Petrushevskaya, which has been applied to Antarctic and Subantarctic deep sea cores. This species comprises a significant portion of the radiolarian assemblage throughout the Pliocene-Pleistocene in Antarctic-Subantarctic cores.

Fig. 1 Map showing location of *Eltanin* cores used in this study and the position of the Antarctic and Subtropical Convergences.

Of the seven cores selected for this study (Fig. 1, Table 1), five are from waters south of Australia (Antarctic waters: E35-6, E36-14, E36-34; Subantarctic waters: E34-14, E36-26) and two are from the central South Pacific (Subantarctic waters: E15-16, E21-17). Four of the five cores south of Australia contain abundant foraminiferal and radiolarian faunas and have palaeoclimatic curves previously established on changes in foraminiferal assemblages². The fifth core, E36-26, has not been previously studied and was selected primarily because it is carbonate free and contains an abundant radiolarian fauna. Subantarctic cores E15-16 and E21-17 have both radiolarian⁹ and foraminiferal¹ palaeoclimatic curves. Two of the seven cores are of Late Pliocene age, and the other five are of Pleistocene age. Palaeomagnetic stratigraphy is available for all the cores^{2,14,15}. For E15-16 and E21-17 the biostratigraphy did

Fig. 2 Nos 1 to 8 *Antarctissa strelkovi* Petrushevskaya: 1, E15-16, 920 to 923 cm, $\times 116$; 2, internal structure, E36-26, 1,222 to 1,224 cm, $\times 107$; 3, internal structure, E36-26, 1,222 to 1,224 cm, $\times 108$; 4, E15-16, 920 to 923 cm, $\times 76$; 5, E21-17, 169 to 171 cm, $\times 92$; 6, E15-16, 920 to 923 cm, $\times 108$; 7, E15-16, 597 to 600 cm, $\times 86$; 8, E21-17, 169 to 171 cm, $\times 88$. Nos. 9 to 12, *Antarctissa denticulata* Petrushevskaya: 9, E36-26, 1,222 to 1,224 cm, $\times 96$; 10, E36-26, 1,222 to 1,224 cm, $\times 84$; 11, showing thoracic plug, E21-17, 169 to 171 cm, $\times 92$; 12, showing thoracic plug, E35-6, 201 to 203 cm, $\times 106$.

not support the palaeomagnetic data, the discrepancy being attributed to the low magnetic intensity in these cores. Thus, the palaeomagnetic stratigraphy for these two cores was inferred from the biostratigraphy¹.

Table 1 Core Parameters

Core	Latitude	Longitude	Water depth (m)	Core length (cm)
E36-26	47° 51' S	155° 05' E	4,691	1,224
E34-14	52° 11' S	145° 03' E	3,264	519
E35-6	53° 12' S	128° 06' E	3,996	600
E21-17	55° 28' S	119° 56' W	2,802	1,004
E15-16	56° 03' S	119° 55' W	3,039	1,200
E36-14	58° 06' S	150° 10' E	3,054	601
E36-34	59° 59' S	155° 02' E	2,794	452

Standard laboratory procedures were followed in the processing of samples and in making faunal slides. Entire slide populations (300 to 1,000 specimens in the $>63 \mu\text{m}$ fraction) were counted for all samples, which were taken at 25 to 40 cm intervals throughout the cores.

Initially, frequency oscillations of *Antarctissa strelkovi* and *Antarctissa denticulata* were investigated. Both forms are consistently abundant throughout the cores. In surface sediments, *A. strelkovi* has its highest frequencies (5% to $>25\%$) in sediments south of 60° S (refs 16 and 17). Petrushevskaya¹⁷ referred to *A. strelkovi* as a high latitude Antarctic species and reported that the distribution of its skeletons in surface sediments of the Southern Ocean corresponds closely with its presence in Antarctic waters. Hays⁴ stated that *A. strelkovi* is probably the most abundant and ubiquitous radiolarian species in the Antarctic, and is the most characteristic species of this fauna. *Antarctissa strelkovi* has also been shown to range from at least the middle of the Gilbert Reversed Epoch to the Recent⁶ ($t=4.0$ m.y. BP to present day). *Antarctissa denticulata* is morphologically similar to *A. strelkovi* and was also

investigated to establish its possible potential as a palaeoclimatic index.

The genus *Antarctissa* is characterised by a compact test, consisting of two segments, the first (cephalis) being somewhat smaller than the second (thorax). The wall of the test has numerous rounded pores, and the surface of the test is generally rough. The internal skeleton consists of

the basic elements typical for nassellarians. *Antarctissa strelkovi* (Fig. 2, Nos 1 to 8) has comparatively thin walls, and the elements of the internal skeleton are more slender and delicate than in *A. denticulata*^{16,17} (Fig. 2, Nos 9 to 12). The massive test of *A. denticulata* has very thick walls, and the thorax is generally closed below by a thick porous plate. The taxonomy and recent distribution of *A. strelkovi*

Fig. 3 Comparison of frequency curves of the radiolarian palaeoclimatic index, *Antarctissa strelkovi* with inferred palaeotemperature oscillations in planktonic foraminiferal and radiolarian assemblages in Southern Ocean deep sea cores. A, Comparison of *Antarctissa strelkovi* and *A. denticulata* frequency oscillations with planktonic foraminiferal palaeoclimatic curves², established in two cores of Late Pliocene–Early Pleistocene age south of Australia; B, comparison of *A. strelkovi* frequency oscillations with planktonic foraminiferal palaeoclimatic curves² in two northern Antarctic cores of Late Pliocene–Pleistocene age from south of Australia; C, comparison of *A. strelkovi* frequency oscillations with inferred palaeoclimatic curves based on planktonic foraminifera¹ and Radiolaria⁹ in two Middle to Late Pleistocene cores from the Subantarctic South Pacific; D, frequency oscillations of *A. strelkovi* in a carbonate-free, Early to Middle Pleistocene Subantarctic core. Warm intervals are numbered in accordance with Keany and Kennett². Palaeomagnetic stratigraphy and assigned ages originally given by Watkins and Kennett¹⁴, Kennett¹ and later utilised by Keany and Kennett². Foraminiferal zones after Kennett¹ and Keany and Kennett²; Radiolaria zones (shown by Greek letters) originally defined for the Antarctic area by Hays⁴ and applied to these cores by Kennett¹, Keany and Kennett² and Huddleston⁹.

This is a new P.A.G.E.

Pharmacia Gel Electrophoresis System for polyacrylamide gradient electrophoresis and other P.A.G.E. techniques

The complete system

Full capabilities for the new pore gradient electrophoresis technique, two dimensional studies, gel rod electrophoresis.

Polyacrylamide gradient gels PAA 4/30

Convenient ready-to-use gradient gel slabs give extreme resolution over the whole range 50,000–2 million MW. Self-limiting migration concentrates the zones after separation by molecular size.

Gel electrophoresis apparatus GE-4

4 gel slabs, 12 samples on each, or 16 gel rod capacity. Robust moulded construction with built-in cooling system. Full range of accessories for all applications.

Electrophoresis power supply EPS 500/400

Compact, all solid state. 0–400 mA constant current, 0–500 V constant voltage with automatic cross-over. Maximum effect 60 W. Full personnel and instrument protection. Available 1974.

Gel destainer GD-4

Electrophoretic or diffusion destaining of slabs or rods in a single operation. Twin cells. Active dye removal and solvent circulation. Results can be inspected at any time.

Destainer power supply DPS

Compact, reliable, all solid state. Push-button selected constant voltages 12, 24, or 36 V. Timer controls electrophoretic destaining up to 90 minutes.

We've invented a speedy "time machine" called Retrospective Search.

This custom service saves you time by searching 1.5 million Life Science articles from the complete indexes to **BIOLOGICAL ABSTRACTS** and **BIORESEARCH INDEX**, 1959 to date.

Instead of spending countless hours searching years of journals, computerized Retrospective Search skillfully selects the abstracts and citations most relevant to your problem—and frees you for more productive work!

Here's how to put our speedy "time machine" to work for you right now—call or write:

Professional Services Dept., BioSciences Information Service, 2100 Arch Street, Philadelphia, Pa. 19103 Phone: (215) 568-4016.

and *A. denticulata* are discussed in detail by Petrushevskaya^{16,17}.

My first faunal counts were made on E34-14 and E36-14, differentiating *A. strelkovi*, *A. denticulata* and other species. Although the *A. denticulata* oscillations (Fig. 3A) show no consistent similarity to the foraminiferal palaeoclimatic curve, the curves representing the percentages of *A. strelkovi* are very similar to those palaeoclimatic curves; the colder the temperature, the greater the percentage of *A. strelkovi*. There is a good correlation (Fig. 3B) between the number and amplitude of warm-water peaks indicated by foraminifera and those described in this paper. Good correlation can also be observed in the two central South Pacific cores (Fig. 3C). In these two cores the similarities between the two curves established using Radiolaria are greater than those between the radiolarian and foraminiferal curves, suggesting slightly different ecological responses for Radiolaria and foraminifera. The potential value of the *A. strelkovi* method is emphasised by its oscillations in a carbonate free core, E36-26 (Fig. 3D), which contains sediments of Early Pleistocene age (zone X to zone Ω ^{4,6}). The palaeoclimatic curve determined for this core is consistent with the palaeomagnetically dated palaeoclimatic curve determined for the Southern Ocean using foraminifera².

In cores of Brunhes and Matuyama age, the curves established using fluctuations in *A. strelkovi* support the conclusions of Kennett¹ and Keany and Kennett³ that the Matuyama was, in general, cooler than the Brunhes in Subantarctic and northern Antarctic areas. In the four cores, the percentage of assemblages represented by *A. strelkovi* on average decreases by 26% from the Matuyama Reversed Epoch ($t=2.43$ to 0.69 m.y. BP) to the Brunhes Normal Epoch ($t=0.69$ m.y. BP to present day). In the three cores which contain carbonate sediments of Brunhes and Matuyama age, the boundary between the *Globorotalia inflata* and the *Globorotalia puncticulata* zones¹ occurs within 50 cm above the X- Ψ boundary^{4,6}, therefore coinciding approximately with the Brunhes-Matuyama boundary. Thus, as suggested by Kennett¹, the *G. inflata*-*G. puncticulata* zonal boundary can be used to approximate the Brunhes-Matuyama boundary in carbonate rich cores from the Southern Ocean.

Palaeoclimatic determinations in Southern Ocean cores using the *A. strelkovi* method are limited to the south by the relatively biogenically barren nature of the cores from the Antarctic shelf and to the north by the northern limit of *A. strelkovi*. Cores from the highest latitudes of the Southern Ocean often produce samples containing fifty or fewer Radiolaria, making it difficult to apply radiolarian palaeoclimatic techniques. The scarcity of the radiolarian tests is due to solution of the siliceous tests, dilution by glacial marine sediments and low productivity. In the northernmost core examined (E36-26, 47° 51' S) *A. strelkovi* is less abundant (1 to 9%), and this core probably lies close to the northern limit of the species.

Obvious anomalies in the data occur in two cores. In Antarctic core E35-6, a warm peak at 200 cm suggested by the foraminifera is not as clear in the *A. strelkovi* curve. In Antarctic core E36-14, two very cold episodes indicated by foraminifera at 250 to 375 cm and 600 cm are not reflected by oscillations in *A. strelkovi*.

Determination of oscillations in the frequency of *A. strelkovi* seems to be a valid and rapid approach for palaeoclimatic determinations in the Southern Ocean. Its value is particularly enhanced by the long range of the species from the Pliocene to the Recent and because many Southern Ocean cores are devoid of foraminifera, especially those of Pliocene age.

I thank J. P. Kennett for advice and discussions. The scanning electron microscope photographs were taken at the University of Rhode Island by Eric Cieplik and Donald

Scales. This research was supported by National Science Foundation grants. The scanning electron microscope facility at the University of Rhode Island was established with the assistance of a grant from the National Science Foundation.

Iceland Mantle Plume

O'HARA¹ has objected to my interpretation concerning the trace element chemistry of lavas erupted along the Iceland-Reykjanes Ridge System² on the ground that: (1) Such magmas are not "primary magmas" but residual liquids; (2) instead, such lavas have suffered prior to eruption extensive "gabbro fractionation" at low pressure (olivine-augite-plagioclase extraction), and/or "eclogite fractionation" at higher pressure (clinopyroxene-garnet extraction in a 50-50% mixture); (3) the "extent of fractionation" is directly proportional to the elevation of the surface on which these lavas have been erupted, thus increases toward Iceland, and is the principal cause of trace element variations along the ridge. According to O'Hara, the lavas are derived from a unique and homogeneous mantle at the upper mantle-transition zone boundary and not, as I prefer², from two distinct mantle sources, one forcefully rising as a primary hot mantle plume (PHMP) beneath Iceland and interacting with the depleted low velocity layer (DLVL).

I answer each of these points in order, concentrating primarily on the rare earth (RE) data which I emphasized², and omitting petrological and isotopic arguments, which will be discussed elsewhere.

Also, several of O'Hara's comments concerning rare earth fractionation are, unfortunately, wrong. For example: (i) Fractional crystallization of clinopyroxene does not deplete but rather enriches a residual melt in lighter rare earths, as is evident from equilibrium partition coefficient data³⁻⁵. (ii) There is no relative Y enrichment towards Iceland, because I did not report nor analyse this element, and my expectation is that it will remain relatively constant, similarly to the heavy rare earths of similar ionic size, such as Er. (iii) There is no massive relative and even absolute depletion of Yb as stated by O'Hara to support his eclogite-fractionation model. The Yb abundance remains relatively constant along the ridge up to Iceland (Fig. 1a). Much of the Yb scatter is in fact analytical, as with the

instrumental neutron activation method used the counting statistics are relatively poor for Yb ($\sigma_{Yb}=15\%$, $\sigma_{La}=9\%$, and $\sigma_{Sm}=2.5\%$). (iv) O'Hara's use of the $[La/Yb]_{EF}$ is misleading since it bypasses the behaviour of intermediate rare earths. This ratio does not adequately contrast the behaviour of the light rare earths relative to the heavy rare earth subgrouping. All the information contained in the rare earth pattern needs to be included to constrain the models.

(1) "Primary magmas". This is a semantics problem. I have

Fig. 1 *a*, Yb against La/Sm enrichment factors relative to chondritic meteorites² in tholeiitic basalts erupted along the postglacial Reykjanes Ridge Axis and its extension over the Middle Neovulcanic Zone of Iceland². +, South of 61°N; ○, 61–62°N; □, 62–63°N; ▤, 63°N to Iceland; ●, Iceland. Dotted area is field of DLVL-derived tholeiitic basalts from other Mid-Ocean Ridges⁶; and dashed area is field for Hawaiian tholeiites³. *b*, Same diagram as above, showing theoretical control liquid lines of descent for fractional crystallization of plagioclase feldspar (Plag), orthopyroxene (Opx), olivine (Ol), clinopyroxene (Cpx) and garnet (Gr). The bar, arrow, half circle, double arrow, filled triangle and point along liquid control lines represent residual liquid composition after fractional crystallisation of respectively 10, 30, 50, 70, 90 and 95 weight % of the corresponding mineral (or bimineralline mixtures for eclogite fractionation—shown as dashed liquid control lines). The large symbols are as given in *a* for the observed values in basalts erupted along the Reykjanes Ridge, but averaged for every degree of latitude. Large arrows: I, the approximate direction of olivine-gabbro fractionation; II, of eclogite fractionation. The lengths are very roughly proportional to the rate of enrichment or depletion for a given degree of fractional crystallisation. Various paths to bridge DLVL-derived melts (+) to PHMP-derived melts (●) can be designed. All these paths require a very unusually large extent of fractional crystallisation of clinopyroxene, and cannot at the same time satisfy the major element chemistry of these two end-member tholeiites (which relative to trace elements represent only small variations). The shaded area takes into account the known range of partition coefficients^{4,8} for plagioclase and the dotted area for the clinopyroxene.

used the adjective "primary" on two occasions to indicate a temporal sequence, where by prior mixing along the transition zone, both PHMP-derived and DLVL-derived melt types are referred as "primary" in contrast to the secondary hybrid lavas resulting from mixing. I did not mean to imply that any of the lavas reported in my paper did not suffer any fractionation prior to eruption, and thus be "primary" in O'Hara's sense. In fact I clearly stated that they are porphyritic in texture, and explained plausible mechanisms by which lavas, once segregated from the residual mantle phases after partial melting during diapiric rise, would accumulate in magma chambers at very shallow depth beneath the thin oceanic crust, cool and begin to fractionally crystallize in order to produce the observed phenocrysts, as well as mix.

Elsewhere⁶ I also used for synonyms⁷ to "primary" the words "principal" melt types, "end-member" melt types, in referring to both PHMP-derived and DLVL-derived tholeiites.

Although we apparently agree that most of these lavas have suffered some crystallization prior to eruption, the question remaining in dispute, I believe, is quantitatively: to what extent are these melts residual, and from what mantle source or sources were they originally derived?

(2) "Olivine-gabbro and eclogite fractionation". I have shown on a $[Yb]_{EF}/[La/Sm]_{EF}$ diagram⁸ the difficulty of bridging by fractional crystallization melts with light RE-depleted pattern (typically mid-ocean ridge basalts, or Reykjanes Ridge south of 61°N) to melts with light RE-enriched pattern (typically island tholeiites, as Iceland), while at the same time keeping $[Yb]_{EF}$ relatively constant. This is shown in Fig. 1*a* and *b*. Only very large amounts of extraction (greater than 90%) of clinopyroxene with rather restricted partition coefficient values (and for that matter also of bulk chemistry) could perhaps bridge both types. This is because operative RE partition coefficients for orthopyroxene, olivine and plagioclase feldspar upon fractional crystallization do not change appreciably the $[La/Sm]_{EF}$ of residual liquids, but merely increase the overall absolute RE abundances (see also Figs 13.15 of ref. 8). Only clinopyroxene is able significantly to fractionate and enrich residual melts in the light RE. On a $[La/Sm]_{EF}/[Yb]_{EF}$ diagram (Fig. 1*b*) the olivine-gabbro liquid-control fractionation line would have to be intermediate between individual controlling lines for plagioclase, olivine and clinopyroxene, and its exact position would depend on the relative proportions of these minerals simultaneously being extracted at the cotectic (see arrow I in Fig. 1*b*). It is clear (Fig. 1*b*) that increasing olivine-gabbro fractionation toward Iceland cannot satisfactorily produce the observed $[La/Sm]_{EF}/[Yb]_{EF}$ variation along the ridge. This, therefore, eliminates one of O'Hara's contentions, that is, an increasing olivine-gabbro fractionation toward Iceland could produce the observed increase of the $[La/Sm]_{EF}$.

So the low pressure olivine-gabbro fractionation can only increase the scatter of $[La/Sm]_{EF}$ towards Iceland, and should be inferred only as a second order effect, as is the eclogite fractionation effect which I now discuss.

Hitherto, I had avoided consideration of the effect of garnet fractionation (although aware of its effect in depleting the heavy rare earths in residual melts having fractionally crystallized garnet⁹) because of the lack of reliable garnet-melt partition data relevant to basalt genesis under eclogitic conditions. In view of O'Hara's remarks, it is necessary to illustrate the control line of liquid descent for eclogite fractionation, using Philpotts's best estimate¹⁰ set of RE partition coefficients for garnet, from the Kakanui region. This set of RE partition coefficient values for garnet gives consistent results with other estimates from other eclogites or garnet peridotites¹⁰. The set is also close to an estimate I had independently made and which is conservative on its effect in depleting the heavy RE. The effect of fractionally crystallizing garnet alone is to deplete drastically the melt in heavy rare earths such as Yb, without changing the $[La/Sm]_{EF}$ appreciably (see Fig. 1*b*). The garnet effect of lowering the $[Yb]_{EF}$ dominates also if garnet and clinopyroxene simultaneously fractionally crystallized from the melt as a 50–50% mixture as

required by O'Hara's eclogite fractionation model¹¹. Again, and contrary to O'Hara's belief, there is no way to match the observed rare earth variation along the Reykjanes Ridge with such an eclogitic fractional crystallization scheme.

Only a mixture composed of 95% clinopyroxene and 5% pyrope garnet could possibly bridge the rare earth pattern variation, but would require some 95% extract of such an unusual mixture. This is of course unacceptable, because the residual liquid of such an extract would have a major element chemistry quite distinct from an olivine tholeiite (the most common lava type over the Reykjanes Peninsula). It would also create a serious volume problem over and above having to explain the two to four times larger flux production of melt in the Iceland Region relative to more normal ridge segments, judging from crustal thickness².

(3) "Extent of fractionation". Although it is true that there is a tendency for increasing fractionation for lava ascending through thicker crust (or altitude), it is untenable that the general trace element geochemical trend observed along the ridge can be accounted for by increasing fractional crystallization alone. As previously noted on the $[La/Sm]_{EF}/[Yb]_{EF}$ diagram, the effect merely increases diversity and scatter about the general trend but cannot be responsible for it. Although at a first glance it may seem that altitude can be correlated with fractionation (such as reflected by the $[La/Sm]_{EF}$), a simple plot of relevant data would show that it is not a regular and simple function. A corollary of my plume model would be that basalt erupted south of 60°N be DLVL-derived and remain light RE-depleted, even though water depth continues generally to increase along the ridge axis. A series of five new rock analyses for stations spaced from 60°N up to the Charlie Gibbs Fracture Zone (~53°N) shows a constant level for the $[La/Sm]_{EF}$ just as south of 61°N (ref. 2, Fig. 3); and therefore further corroborates my model for two mantle sources of different densities and differentiation history.

O'Hara's preferred model of a single mantle source at the upper mantle-transition zone boundary^{11,12} offers little substance for discussion here, as it does not take into consideration the many geophysical-geochemical and geological features which contrast Iceland with the Mid-Atlantic Ridge. I do wish to emphasise that any alternative to my model should also satisfy these many model requirements, which I have listed and have taken into consideration in my model².

Contrary to O'Hara's belief, I rejected the model of a single mantle source with increasing degree of fractional crystallization toward Iceland not only on the basis of isotopic ratios (evidence which for two mantle sources is overwhelming¹³), but also from rare earth considerations as outlined above and which I had to omit in my original discussion² for the sake of brevity.

Cavitation as a Mechanism for the Synthesis of Natural Diamonds

LET us grant, in accordance with Galimov's proposals¹, that cavitation can occur when flowing magma in a pipe encounters a constriction, and that in the ensuing collapse of a bubble very substantial transient dynamic pressures, of magnitude sufficient to be of thermodynamic importance for diamond synthesis, can be produced. In granting this, we overlook some quantitative details in his calculation, such as the apparent implication that the bubbles would contain gas at 10 or 20 kbar, and yet that their compression (by a factor of 64,000 in volume) can be calculated by ideal gas theory. He ignores the fundamental difference in rate control between martensitic conversion of crystals from one modification to another, which makes a product of the same chemical composition as the starting material, and other processes of crystal growth requiring a composition change. In the former class, to which production of diamond by the action of shock waves on graphite belongs, the limit on growth velocity is essentially the shock wave velocity. Thus, so far as that is concerned, quite a large diamond might be made within a few microseconds. Further characteristics of martensitic processes are, however, that the product takes the form of thin lenses, whereby the constraint by the matrix on shape change in the converting region is minimised and, second, that as a rule there is a multiplicity of orientations of the martensitic product in the parent crystal, so that a microcrystalline product results.

If the product is not to have the same chemical composition as the starting material, time must be allowed for diffusive segregation of chemical constituents. Galimov estimates the duration, t_{coll} , of dynamic pressure due to bubble collapse as 2×10^{-8} s. In this time diffusive segregation could occur through a thickness of order $x = (Dt_{coll})^{1/2}$, where D is the diffusion coefficient. With a fairly generous allowance of $10^{-4} \text{ cm}^2 \text{ s}^{-1}$ for D we have $x \sim 4.5 \mu\text{m}$. The thickness of diamond which could grow from one seed in the given time could not exceed this and would be proportionately less in a medium of low concentration of carbon. Of course, repeated cavitations could give repeated periods of growth, but there is no apparent reason why re-solution would not occur in the much longer intervening periods of diamond instability. Galimov offers no estimate of the carbon content of the medium, except to indicate that 30% is too much. (There are, incidentally, no grounds whatever for his idea that a supersaturated solution of carbon from which diamond could grow would need a carbon concentration of this order of magnitude.)

Thus it is conceivable that some microdiamonds are produced under dynamic pressures due to cavitation in a fast flowing magma, either embedded in graphite or otherwise: and whereas the former might survive it is highly unlikely that the latter would. But it is quite certain that the recognised diamonds for which diamond mines are worked were not produced by this process. These diamonds, of fairly equant habit, and of dimensions of millimetres to centimetres as well as smaller, frequently show inescapable evidence of growth in successive shells on all sides, with discontinuities in the growth conditions, but continuity through thicknesses of tens or hundreds of micrometres, as well as (usually terminal) periods of resolution²⁻⁶. These internal variations of impurity content and texture are readily explained by growth from solutions in times of at least the order of an hour, but quite inexplicable in terms of production by transient dynamic shock pressure.

In brief, the sole basis of Galimov's claim, in connection with his postulated mechanism, that "there are no limitations involving the total concentration of carbon in the medium" is his complete disregard of such limitations, which are inescapable.

BIOLOGICAL SCIENCES

A Novel Substituted Guanidine with High Activity *in vitro* against Rhinoviruses

THE number and diversity of the viruses which infect the upper respiratory tract, and cause the common cold, virtually preclude the control of this disease by conventional vaccines. From this, apart from symptomatic therapy, the only hope for effective treatment of this most prevalent of diseases is in the development of broad spectrum antiviral drugs. We have developed a substituted guanidine, ICI 65,709 (ref. 1) (Fig. 1) which has good activity *in vitro* against all twenty-five rhinovirus serotypes tested in human embryonic lung cells, and also against certain other picornaviruses.

Fig. 1 The structural formula of ICI 65,709; 1-*p*-chlorophenyl-3-(*m* isobutylthioureido) phenyl guanidine hydrochloride.

The method of testing for antiviral activity has been fully described^{2,3}. In brief, it consists of infecting tissue-culture cells in 3×0.5-inch tubes with 100 TCD₅₀ of test virus, and then adding the test compound in a range of concentrations. After incubation at 33° C for 2 d, the cells are inspected with a low power microscope and the concentration of compound which causes 50% cytotoxicity and that which causes 50% inhibition of virus growth (cytopathic effect) are determined. From these values a tissue-culture 'therapeutic ratio' is calculated for each virus tested.

Table 1 shows that although the range of viruses tested was limited, it is clear that the activity of the compound is not confined to the rhinoviruses. Certain other picornaviruses were sensitive, and there was also some activity against vaccinia, herpes simplex, and the two arboviruses tested. The compound was inactive against equine rhinovirus, respiratory

syncytial virus and the 229E strain of coronavirus, and also against influenza or parainfluenza grown in calf kidney cells.

A curious feature of the compound was that its antiviral action was highly dependent on the type of cell in which it is tested. For example, although the growth of rhinovirus type 2 in human embryonic lung cells is strongly inhibited by ICI 65,709, the same virus grown in KB cells, HeLa or primary rhesus monkey kidney cells is completely insensitive to the compound. When rhinoviruses are grown in fragments of human embryonic trachea, 1 μg ml⁻¹ ICI 65,709 inhibits growth by approximately 90%.

Table 1 50% Toxic and 50% Antiviral Concentrations of ICI 65,709 Against Various Viruses

Cell type	50% toxic concentration (μg ml ⁻¹)	Virus	50% antiviral concentration (μg ml ⁻¹)	Therapeutic ratio <i>in vitro</i>
Human embryonic	6	Rhinovirus type 6, 5, 35	0.4	15
		33, 3, 44, 40, 1A, 9, 43	0.2	30
		32, 14, 29, 27, 11, 1B, 2	0.1	60
		15, 16, 31, 4, 26, 36, 17	0.05	120
		Equine rhinovirus	Not active	—
		Echovirus type 11	0.05	120
		14	0.1	60
		Coxsackie virus type A9	0.4	15
		A21 (Coe)	0.8	7
		B3	0.1	60
		Vaccinia	0.2	30
		Herpes viruses:		
		H. simplex type 1	1.0	6
		H. simplex type 2	1.0	6
		Pseudorabies	Not active	—
Primary calf kidney	12	Semliki forest	0.8	7
		Sindbis	0.8	7
		Influenza A ₀	Not active	—
		A ₁	Not active	—
		A ₂	Not active	—
		Parainfluenza 1	Not active	—
		Respiratory syncytial	Not active	—
		Coronavirus 229E	Not active	—

Studies on the mode of action of ICI 65,709 using rhinovirus type 2 in human embryonic lung cells have shown that the compound does not destroy the rhinovirus virion, nor does it prevent the attachment or penetration of virus particles into the host cell. When the compound is added to virus-infected cells at various times after infection, and the virus yields at the end of the first growth cycle are measured, the compound is seen to exert progressively more inhibition of virus growth the longer it is present on the infected cell. This suggests an effect on a virus synthetic process which begins soon after eclipse and continues throughout the replicative process: possibly virus RNA or protein synthesis. The compound has no inhibitory effect on the RNA or protein synthesis of the host cell at concentrations up to 100 times the 50% antiviral level.

Although ICI 65,709 is a derivative of guanidine, its antiviral action differs from that of guanidine⁴ in at least two ways. First, it does not give rise to drug-resistance as does guanidine, and second, its action is not reversed by substances such as ethanolamine, choline, methionine, or lactalbumin hydrolysate⁵⁻⁸. Biochemical studies (Kolias, S. I., and Dim-

mock, N. J., unpublished) also suggest that ICI 65,709 differs in its mode of action from guanidine.

C-reactive Protein-like Precipitins in Plaice

C-REACTIVE protein (CRP) is an acute phase protein appearing in the serum of man during the febrile stage of infections with pneumococci and various other microorganisms^{1,2}. The protein can also be detected in serum and other serous fluids during pathological conditions in which tissue injury, inflammation or carcinoma are involved^{3,4}. Acute phase proteins have also been detected in the sera of a number of other vertebrates, including monkeys, rabbits and mice⁵, but there seem to be few reports of these proteins in lower vertebrates⁶.

In the presence of Ca²⁺, CRP is precipitated from solution by pneumococcal C-substance^{1,7} and also by extracts from a number of fungi, invertebrates and plants⁸⁻¹⁰. Following the demonstration that various phosphate monoesters inhibit the CRP-C-polysaccharide precipitation reaction¹¹, phosphorylcholine has recently been found to be the most active inhibitor of all the compounds so far tested¹².

Using extracts from *Diplococcus pneumoniae*, some fungi and a nematode, *Ascaris lumbricoides*, together with a peptido-polysaccharide isolated from the dermatophyte *Epidermophyton floccosum*, we have found a CRP-like serum component in the plaice (*Pleuronectes platessa* L.), a marine teleost. We describe here specificity studies carried out with the plaice precipitin and discuss the origin and possible biological role of such proteins in poikilotherms.

Fish were caught in shallow water off the coast of Aberdeen and transferred to aerated seawater at 11–14° C in the aquarium. Single serum samples were collected¹³ between 1 h and 4 months after the capture of the fish. Human serum containing CRP was obtained from the Brompton Hospital, London, from patients with pulmonary diseases. The presence of CRP in the human samples was established by precipitation with rabbit anti-CRP (Behringwerke). Aqueous extracts of *D. pneumoniae*, *E. floccosum*, *Aspergillus flavus*, *Aspergillus fumigatus*, *Trichophyton mentagrophytes*, *T. rubrum* and *A. lumbricoides* were prepared from culture filtrates and minced worms by methods already described^{1,8,14}.

Precipitation studies with con A have shown that this reagent reacts with polysaccharides from a variety of fungi including *E. floccosum* and a number of *Aspergillus* and *Trichophyton* species

(B. A. B. and J. Pepys, unpublished). A peptido-polysaccharide was isolated from *E. floccosum* by passage of the aqueous extract through a column of Sepharose-con A (Pharmacia) and elution of the adsorbed material with 0.1 M α -methyl-mannopyranoside in physiological saline. After dialysis and lyophilisation, the peptido-polysaccharide was used in precipitation studies.

Forty-four of forty-seven different plaice sera examined (from thirty males and females of approximately 2 to 7 yr and seventeen O-group plaice) precipitated in gel with *E. floccosum* extract. The sera also precipitated with the peptido-polysaccharide and the lines were completely confluent with those formed with culture filtrate extracts from the five fungi examined and extracts from *A. lumbricoides* and *D. pneumoniae*. The precipitin reactions observed when plaice serum and human CRP-containing serum were examined in gel diffusion experiments with some of the extracts are shown (Fig. 1a and b). As with the plaice serum, the human serum formed a continuous line of precipitation with all of the extracts. When the plaice and human sera were examined side by side in gel with *E. floccosum* peptido-polysaccharide, *E. floccosum* culture filtrate extract and pneumococcus extract, precipitation occurred in front of each of the peripheral wells and the precipitin lines merged with no sign of spurring (Fig. 1c).

Our evidence supports the view that the precipitins in the plaice sera are not antibodies. Immersion of the gels in 5% sodium citrate or 0.1 M EDTA in physiological saline caused the disappearance, within 30 min, of the lines between the plaice serum and human CRP and the pneumococcus, fungal and *Ascaris* extracts. In contrast, citrate or EDTA did not affect the precipitin reaction observed between *Vibrio anguillarum* extract and serum from a plaice previously immunised with this antigen¹⁵. Immunoelectrophoresis of whole plaice serum in Ionagar at pH 8.6 followed by development against *E. floccosum* culture filtrate extract or peptido-polysaccharide revealed a precipitin line in the α_2 -region, and antibody activity was associated with an immunoglobulin migrating in the β -region. The plaice and human CRP precipitin lines were dissolved within 2 h after immersion of the gels in 0.001 M phosphorylcholine in physiological saline. The lines were not soluble in 0.002 M solutions of choline chloride, α -D-glycerophosphate, AMP, CMP, UMP, glucose-1-phosphate, glucose-6-phosphate or in phosphate-buffered saline. Precipitation of plaice serum with *E. floccosum* peptido-polysaccharide and inhibition of this reaction with phosphorylcholine was confirmed with quantitative studies. In a typical experiment (Table 1), 200 μ l of plaice serum produced maximum precipitation (2.6 μ g of protein N) with 1,086 μ g of *E. floccosum* peptido-polysaccharide. Using these quantities of reagents, inhibition studies revealed that precipitation could be partially inhibited (76%) by 1 μ mol of phosphorylcholine and completely inhibited by 10 μ mol.

Table 1 Precipitation of *Epidermophyton floccosum* Peptidopolysaccharide by Plaice Serum

Peptido-polysaccharide used (μ g)	N in precipitate (μ g)
108.6	0.42
217.2	0.76
543.0	1.90
760.2	2.30
1,086.0	2.55
1,303.2	2.42

Quantitative precipitin analysis was carried out using a micro-precipitin technique and ninhydrin procedure for nitrogen determination²¹. Volume of serum per tube, 200 μ l. Total volume, 350 μ l.

The finding of CRP-like precipitins in the sera of apparently healthy male, female and young plaice, together with the fact that these precipitins were detected in almost all of the fish examined, suggests that this protein may be a normal component of plaice serum and not arise, as in higher vertebrates, only after infection or trauma. Some of the plaice examined had been in the aquarium for 4 months and were feeding

Fig. 1 Agar gel diffusion patterns formed from the reactions of plaice serum and human serum containing C-reactive protein with extracts from some fungi, *Ascaris lumbricoides* and *Diplococcus pneumoniae*. *a*, Centre well, plaice serum; peripheral wells, 1, *E. floccosum* peptido-polysaccharide 10 mg ml⁻¹; 2, *E. floccosum* extract 20 mg ml⁻¹; 3, *A. lumbricoides* extract 20 mg ml⁻¹; 4, *A. fumigatus* extract 20 mg ml⁻¹; 5, *T. mentagrophytes* extract 20 mg ml⁻¹; 6, *E. floccosum* peptido-polysaccharide 10 mg ml⁻¹. *b*, Centre well, human serum containing C-reactive protein; peripheral wells as for *a*. *c*, Peripheral wells 1, 3, 5, and 7, *E. floccosum* extract 23 mg ml⁻¹; 2, 6, *D. pneumoniae* extract 20 mg ml⁻¹; 4, 8, *E. floccosum* peptido-polysaccharide 11 mg ml⁻¹. Centre wells, 9, human serum containing C-reactive protein; 10, plaice serum.

regularly, which would suggest that they had recovered from the possible initial trauma of capture. Our preliminary studies have shown that sera from dab (*Limanda limanda* (L.)) and cod (*Gadus morrhua* L.) also contain fungal precipitins soluble in 5% sodium citrate solution. Specificity studies on these precipitins are in progress.

The ability of poikilotherms to mount a potent antibody response is now well established¹⁵ but it is also clear that antibody production is often restricted at low temperatures^{16,17}. In its natural environment the plaice is commonly found at temperatures of 10° C and below and at these lower temperatures non-antibody precipitins might provide a valuable adjunct to the animal's defences against infection. In these circumstances it would be advantageous for primitive vertebrates to have

serum proteins with broad specificity for determinants commonly found in the cell walls or surface structures of invading organisms. Phosphorylcholine may be such a widely occurring determinant as its presence in antigens from a number of bacteria, fungi and parasites has recently been suggested by precipitation results obtained with mouse anti-phosphorylcholine myeloma proteins^{18,19}. The possibility therefore exists that non-antibody precipitins form part of the fishes' humoral defences against invasion by microorganisms and parasites. Evidence of a possible anti-bacterial role for human CRP has recently been presented²⁰.

We thank Professor J. Pepys for helpful discussion and support.

Inhibition of Local Graft-versus-Host Reaction by Anti-Alloantibodies

THE variable part of an antibody molecule can be used as an antigen within the species that produces it. Antibodies against such variable part antigenic determinants (idiotypes) are called anti-idiotypic¹. One example of anti-idiotypic antibodies is found in alloantibody systems, where A anti-B antibodies directed against histocompatibility antigens can be shown to elicit the formation of anti-alloantibodies when injected into (A × B) F₁ hybrids^{2,3}. That the hybrid indeed synthesises anti-alloantibodies has been demonstrated both by studies on the kinetics of formation⁴ and on the allotypic specificity⁵ of the F₁ product. Such anti-alloantibodies can be shown to

react not only with humoral alloantibodies³, but also with cells carrying receptors (recognition structures) of the same idiotype specificity². The possibility of using anti-alloantibodies for highly selective immunosuppression of transplantation reactions *in vivo* is of obvious importance. We have therefore attempted to prevent a local graft-versus-host (GvH) reaction in rats by anti-alloantibody.

Rats of the inbred strains Lewis and DA, differing at a major histocompatibility locus⁶, and their hybrids were used. Lewis anti-DA and DA anti-Lewis alloantisera were obtained 24 d after grafting DA skin on Lewis hosts and *vice versa*. These sera served to immunize two groups of 5 to 8 week old (Lewis × DA) F₁ animals. Each animal received five intradermal injections of 0.2 ml of alloantiserum in the skin of its belly on day 0, and 1.0 ml of the same alloantiserum intraperitoneally on day 14. An average of 2 ml of blood was obtained from half of the animals in each group on day 21, to be used later in passive immunisation experiments. Later on the same day 5 × 10⁶ viable normal Lewis spleen and lymph node cells were injected into one hind foot, and the same numbers of DA lymphoid cells were injected into the other hind foot of each immunised F₁ hybrid. 7 d later, the popliteal lymph nodes were excised and weighed⁷.

Table 1 Weights (mg) of Popliteal Lymph Nodes of (Lewis × DA) F₁ Rats Actively Immunized with Lewis Anti-DA Alloantibody

Viable lymphoid cells from strains Lewis and DA were injected into opposite feet. The corresponding popliteal lymph nodes were excised 7 d later.

* Significantly different from 0 ($P \leq 0.01$).

Table 1 shows that in F₁ animals immunised with Lewis anti-DA the node responding to the injection of Lewis cells was significantly smaller than the node corresponding to the injection of DA cells. Conversely, in animals immunised with DA anti-Lewis, the DA node was smaller than the Lewis node (Table 2). Non-stimulated lymph nodes in rats of the same age, however, averaged 7 mg and were thus considerably smaller than the "inhibited" nodes in Tables 1 and 2, indicating that this inhibition was relative but not complete.

We concluded from this experiment that in animals actively immunised with alloantibody, the GvH reaction induced by parental lymphoid cells was specifically reduced by anti-alloantibody. Other interpretations, however, might be offered. It could be argued that the injected A anti-B alloantibody itself covered certain antigenic B sites in the F₁ host, thereby impeding stimulation of A cells by these antigens.

To test this alternative hypothesis, passive immunisation with variously absorbed anti-alloantisera was arranged. Serum pools obtained from the immunised F₁ animals used in the first experiment will be referred to as anti-(Lewis anti-DA) (Table 3) and anti-(DA anti-Lewis) (Table 4), respectively.

Both sera were twice absorbed with 20 × 10⁶ (Lewis × DA) F₁ lymphoid cells ml⁻¹ to eliminate possible remnants of the alloantibodies used to immunize the animals. Each serum was then subdivided into three parts of 4 ml each. One part was left untreated, A, the other part was absorbed three times with 20 × 10⁶ Lewis lymphoid cells ml⁻¹ for 15 min, B, and the third part was similarly absorbed with DA lymphoid cells, C. Each sample was then injected intraperitoneally into four normal (Lewis × DA) F₁ hosts (1 ml per rat). Four hours later, 5 × 10⁶ viable parental lymphoid cells were injected into the hind feet of each passively immunised animal, as done in the first experiment. After 7 d, the popliteal nodes were excised and weighed.

Table 2 Weights (mg) of Popliteal Lymph Nodes from (Lewis × DA) F₁ Rats Actively Immunized with DA Anti-Lewis Alloantibody

Lewis node	DA node	Ratio Lewis/DA	Mean log ratio ± s.e.

* Not significantly different from Table 1; significantly different from 0 ($P < 0.05$).

† Not significantly different from 0; significantly different from Table 1 ($P < 0.05$).

Tables 3 and 4 show that the inhibition of GvH reactivity could be passively transferred with antiserum, even though this serum had been obtained from F₁ animals and had, in addition, been absorbed with F₁ cells and was thus presumably free of the last traces of the originally injected alloantibody (groups A of Tables 3 and 4).

Comparison of groups A in Tables 3 and 4 with Tables 1 and 2 shows that passive immunisation led to lymph node weight ratios not significantly different from those obtained in actively immunised rats. Absorption with cells from the strain against which the original alloantibody was directed (Table 3C and Table 4B) likewise failed to produce a significant change in weight ratio from that of actively immunised rats. In contrast, absorption with lymphoid cells from the strain which had produced the alloantibody abolished the inhibitory activity, making the mean lymph node weight ratios (Tables 3B and 4C) close to one. Such a ratio of one is found in the present strain combinations when using the same number of normal parental cells into normal F₁ hybrid recipients. This, then, must mean that the lymphoid cells used for absorption in Tables 3B and 4C carried receptors of the same idotype as the humoral alloantibody.

We interpret these findings in the following manner. Inhibition of the local GvH reaction by anti-alloantibodies cannot be explained in terms of residual alloantibody coating relevant target sites. Rather, an effect on the specific receptors for antigen on the parental lymphoid cells has to be envisaged. It is therefore likely that circulating alloantibodies induced by an allogeneic skin graft and certain receptors active in local GvH reaction share idotypic determinants.

Our data support and extend the finding that a lethal GvH disease could be prevented by antiserum directed at recognition structures of attacking cells⁸. "Selective immunological disarmament"⁹ would thus seem to be feasible *in vivo*. This is also confirmed by two recent abstracts^{10,11} and by unpublished observations (S. Zakarian, personal communication).

Table 4 Weights (mg) of Popliteal Lymph Nodes of (Lewis × DA) F₁ Rats Receiving Anti-idiotypic Antibodies made in (Lewis × DA) F₁ Rats Against DA Anti-Lewis Alloantibodies

A, F₁ animals passively immunised with anti-(DA anti-Lewis) absorbed with F₁ cells only.

† Not significantly different from 0; significantly different from Table 2 ($P < 0.05$).

Finally, from the present data we cannot decide whether B and T cells reactive against the same histocompatibility antigens use receptors of the same idotype. Purified B and T cell populations will have to be used to decide the issue. Meanwhile all that can be said is that the local popliteal lymph node assay has been considered to measure in a rather exclusive manner the reactivity of specific T cells⁷.

Differential Staining of Nucleolus Organisers in Mammalian Chromosomes

THE *in situ* DNA-RNA hybridisation techniques to locate a certain genome fraction with unique nucleotide sequences¹⁻⁶ have assigned ribosomal cistrons to the satellites of human D and G group chromosomes^{4,5}. This is of particular interest because the satellites organise nucleoli in somatic⁷ and meiotic cells⁸⁻¹⁰. During the course of study on the Giemsa banding mechanism (unpublished) we found that the satellite bodies of human acrocentrics can be differentially stained with Giemsa after simple procedures including extraction of both nucleic acids and histones. The staining profile, herein referred to as 'N band', differed clearly from the Quinacrine, Giemsa, Reversed-Giemsa, Centromeric, or Giemsa 11 banding patterns^{11,12}. In rat kangaroo chromosomes, the N bands appeared exclusively in the nucleolus organisers^{13,14}, that is, in the secondary constriction of the X chromosome. Further application of this technique to other mammalian species strongly indicated that the N-band-positive sites coincide with nucleolus organisers.

Air-dried or flame-dried chromosome slides were prepared from various cell sources: cultured human lymphocytes, a subline of the rat kangaroo (*Potorous tridactylus*) cell line Pt-K₁, an Indian muntjac (*Muntiacus muntjak*) cell line KLS (established in our laboratory), rat (*Rattus norvegicus*) lung fibroblasts, a Chinese hamster (*Cricetulus griseus*) cell line DON, monkey (*Macaca fascicularis*) lung fibroblasts, embryonic mouse (*Mus musculus*) cells and mouse testis

cells^{15,16}. The slides were incubated in 5% trichloroacetic acid (TCA) for 30 min at 85–90° C, briefly rinsed in tap water, and reincubated for 30–45 min at 60° C in 0.1 N HCl. The slides were then thoroughly rinsed in tap water and stained for 60 min with phosphate-buffered Giemsa (diluted 1:10), pH 7.0. Digestion of chromosomes with DNase (100 $\mu\text{g ml}^{-1}$ for 60 min at 37° C at pH 6.6) and RNase (pancreatic RNase A; 100 $\mu\text{g ml}^{-1}$ for 60 min at 37° C at pH 7.0) could be substituted for the TCA step.

In well spread human metaphase plates, the N bands appeared as distinctive purplish red spots restricted to the satellite regions of all acrocentric chromosomes (Fig. 1), whereas no such deeply stained bands were observed in any other chromosome or chromosomal region including the secondary constrictions of chromosomes 1, 9 and 16. Application of the Quinacrine staining method¹⁷ before the N staining showed unequivocally that N bands were located exclusively on the satellites but not on the centromeres, short arms or stalks of satellites (Fig. 2a, b). It was obvious that even negatively or faintly fluorescent satellites could be visualised by the present technique. Although two N-band spots on each acrocentric were usual (Fig. 2b), they were frequently fused to form one spot (Fig. 1). The variation in size and number of N bands in different acrocentric members as well as in different individuals apparently reflects the genetic polymorphism which may serve as an excellent genetic marker. On the other hand, in almost all nuclei of interphase human lymphocytes the N bands appeared as tiny spots clustering within the nucleoli (Fig. 3a). Such clustering was conspicuous until late prophase when the chromosomes began metaphasic orientation (Fig. 3b).

Fig. 1 Metaphase chromosomes of a human male shown by the N-staining method.

In the rat kangaroo metaphase chromosomes, N bands were clearly visible at the secondary constriction of the X chromosomes (Fig. 4a), apparently coinciding with the nucleolus organisers^{13,14}. Indian muntjac and monkey chromosomes were also tested, as they have conspicuous secondary constrictions in certain chromosomes^{18–20}. Although their nucleolus organisers have not been located in prophase nuclei, the exclusive detection of N bands in the secondary constrictions (Fig. 4b) and interphase nucleoli was notable. In the rat and Chinese hamster chromosomes the telomeric ends and centromeres of certain bi-armed and telocentric elements were shown to be nucleolus organisers

Fig. 2 A partial male karyotype of man, by Quinacrine staining (a) and N-staining (b) methods. A satellite association (upper right, b) is clearly demonstrated (long arrow).

in the prophase nuclei, as in other species^{13,21}, and to be N-band-positive. In the mouse chromosomes, however, the N band was similar in appearance to the C band, though the former appeared to be smaller and located at the centromeric end (Fig. 4c). In Sertoli cells of the mouse testis, the C-band-positive heterochromatins²² were entirely N-band-negative (Fig. 4d). As in the case of human cells, interphase cells of all the animals tested here showed deeply stained N-band figures clustering exclusively within the nucleoli. The above observations strongly suggest that in these animals all N-band-positive sites coincide with nucleolus organisers.

Since our technique was devised to extract both nucleic acids and histones in histological preparations²³, the N-band substances were thought to be acidic proteins. This was supported by several tests. First, chromosomes treated with TCA and HCl were all negative for Feulgen, methyl green-pyronin, alkaline fast green (pH 8.0)²⁴, ammoniacal silver²⁵ and PAS stainings. Second, chromosomes digested with proteolytic enzymes such as Pronase (Kaken, Tokyo; 100 $\mu\text{g ml}^{-1}$ for 10 min at 37° C) or trypsin (Sigma; three times crystallised; 10 $\mu\text{g ml}^{-1}$ for 10 min at 37° C) did not show the N band. Third, treatment with 0.1 N NaOH for 1 min

Fig. 3 Cultured human interphase lymphocyte stained by the N-banding method.

Fig. 4 N bands from: *a*, rat kangaroo (partial metaphase of a triploid subline of Pt-K₁ with three X chromosomes); *b*, Indian muntjac; *c*, embryonic cell of the mouse; *d*, mouse testis, showing negatively stained C bands in Sertoli cells (arrowed). The N-band cluster is obvious in the nucleoli.

after the TCA and HCl steps abolished N-band staining, whereas treatment with 0.2 N H₂SO₄ after the TCA and HCl steps did not change N-band staining.

Although the mechanism involved in the N-staining procedure remains uncertain, it is interesting that acidic proteins may be involved in the expression of ribosomal cistrons in mammalian nuclei. N bands may provide useful genetic markers, and we are investigating further their cytogenetic and biochemical properties.

Why Centric Regions of Quinacrine-treated Mouse Chromosomes show Diminished Fluorescence

Rowley and Bodmer¹ reported that the centric regions of quinacrine-treated mouse chromosome preparations show less fluorescence intensity than the remainder of the chromosome. They argued that because these centric regions contain a type of DNA that is richer in AT base pairs than unique sequence DNA, they would be expected to show diminished fluorescence according to the model proposed by Caspersson *et al.*², according to which localised quinacrine fluorescence was attributed to the preferential binding of quinacrine mustard to the N-7 position of guanylyl residues in DNA. Thus, one would expect a relative paucity of guanylyl residues in the DNA of the centric regions to be associated with diminished fluorescence. It has since been shown^{3,4} that enhanced quinacrine fluorescence is due to AT base pairs, and studies of a series of GC-containing DNA polymers indicated that GC base pairs (or G alone) actually quenched fluorescence⁴. These observations did not explain why the centric regions of mouse chromosomes with their relatively greater abundance of AT base pairs show diminished quinacrine fluorescence.

Table 1 Effect of DNA Polymers on Quinacrine Fluorescence

DNA polymer added	mol % G+C	Fluorescence	Fold over control
None	—	35	0
(dA) _n ·(dT) _n	0	85	+1.4
(dG) _n ·(dC) _n	100	10	-0.7
(dA) _n ·(dT) _n + (dG) _n ·(dC) _n (1:1 mixture)	50	55	+0.6
<i>E. coli</i> DNA	52	5	-0.9
<i>C. perfringens</i> DNA	32	30	-0.1

DNA polymers (10⁻⁴ M, phosphate basis) were mixed with quinacrine (2 × 10⁻⁶ M) in 0.1 M (Na) phosphate buffer, pH 6.8. Excitation was at 425 nm and fluorescence was measured at 490 nm.

To answer this question we examined further fluorometric properties of quinacrine in the presence of DNA polymers (Table 1). (dA)_n·(dT)_n enhances quinacrine fluorescence while (dG)_n·(dC)_n quenches fluorescence. A 1:1 mixture prepared by mixing equal volumes of these two samples still enhances fluorescence but with diminished efficiency, presumably due to dilution. In any case, the net effect is still one of enhancement by an equimolar mixture of polynucleotides which gives a final GC concentration of 50 mol%. In contrast, DNA from

Escherichia coli which contains 52 mol% GC quenches quinacrine fluorescence, as does DNA from *Clostridium perfringens* with 32 mol% GC.

These observations suggest that the degree of fluorescence enhancement is not strictly a function of the AT/GC ratio but that the degree of interspersed of GC base pairs among AT base pairs plays an important role. Thus, in a comparison of two polynucleotides with the same base composition, the one which has a higher degree of GC base pair interspersed would be expected to show a greater degree of quenching. A corollary would be: for two polynucleotides with different base compositions, the polynucleotide with less GC could actually quench more if the GC base pairs were more evenly interspersed (compare *C. perfringens* DNA and $(dA)_n \cdot (dT)_n + (dG)_n \cdot (dC)_n$). An extreme example of GC interspersed would be one in which GC (and therefore AT) base pairs were distributed evenly throughout the length of the polynucleotide. Such DNA would be highly repetitive, a well known property of the DNA found at the centric regions of mouse chromosomes.

Caspersson and Zech⁵ originally proposed that preferential binding to accessible sites is the determinant of quinacrine fluorescence. In a recent work⁵ the possibility of quinacrine fluorescence enhancement by AT-groups and quenching by GC groups is acknowledged. On the other hand, our fluorometric studies of dyes that bind to DNA lead us to the conclusion that for those dyes which have useful fluorescence staining properties for chromosomes, the fundamental determinants of the fluorescence pattern seen are the bases and their relation to each other; both the primary and secondary structures can play a role. Whether the fluorometric properties of the dye are actually expressed may depend on secondary factors such as accessibility, controlled by unidentified hypothetical proteins. The results described here exemplify a further application of this principle.

Cytosine Arabinoside and Rosette Formation in Mouse Retina

Glücksman and Tansley¹ reported that the developing retina was very vulnerable to X rays and this has been confirmed by many other investigators²⁻⁴. Some drugs which inhibit DNA synthesis may also inhibit cellular proliferation and thus cause maldevelopment of the retina. This would result because, in the neural retina of the suckling animals, active cellular proliferation is taking place producing neurones at the inner and outer nuclear layers^{5,6}.

Cytosine arabinoside, a common antitumour drug, inhibits DNA polymerase^{7,8}. Because of this, it is used in the treatment of some viral infections, such as herpesvirus infection⁹⁻¹¹ and cytomegalic inclusion disease¹². We have investigated the possible effects of this drug on the developing mouse retina.

One hundred and twenty-one suckling mice, ICR-JCL

Fig. 1 A, Normal retina of 20-d-old mouse. G, Ganglion cell layer; Ip, inner plexiform layer; In, inner nuclear layer; Op, outer plexiform layer; On, outer nuclear layer. B, Retina of 20-d-old mouse which had three successive doses of (50 mg kg⁻¹) cytosine arabinoside on postnatal days 2, 3 and 4. R, Rosette; Hg, heterotopic ganglion cell in the inner plexiform layer.

strain, were divided into two groups. Forty-seven mice were injected subcutaneously with cytosine arabinoside (30 mg kg⁻¹) 2, 3 and 4 d after birth (group 1). Seventy-four animals were similarly treated with 50 mg kg⁻¹ (group 2). Treated animals of both groups were then killed 5, 7, 10, 15, 20 and 30 d after birth. The eyes were removed, fixed in either Bouin's or Carnoy's solution, embedded in 'Paraplast' and cut into 6 μ m sections. The sections were stained either with haematoxylin-eosin or 1% cresyl violet. Retinas of untreated mice of the same age were used as controls.

Twenty-four hours after the final injection of cytosine arabinoside the undifferentiated nuclear layer was seen to be selectively destroyed and to contain a large quantity of nuclear debris. Large cavities resulting from the necrosis of undifferentiated cells were also prevalent in this layer. In the retina of 5-d-old controls many large, round, pale nuclei, which later formed the inner nuclear layer, were seen at the inner zone of the undifferentiated nuclear layer. On the outer surface of this layer, however, mitosis was still common. When the experimental animals were examined on postnatal day 7, the nuclear debris and cavity in the nuclear layer had disappeared although many rosettes were found, either scattered or in rows, at the outer nuclear layer. A few cells in mitosis were found on the inner surface of this structure. By this time the retina of a 7 d old control was already similar to that of an adult. Even 20 and 30 d after birth, rosettes were found in 81 to 67% of the retinas in group 1 and in all of group 2 (Table 1). They were especially numerous on the portion of the retina close to the ora serrata. The ganglion cells of the treated mouse were arranged irregularly and the inner plexiform layer was approximately twice as wide as that of the controls. Within the inner plexiform layer, heterotopic cells, which are morphologically similar to ganglion cells, were found in clusters or in rows (Fig. 1).

Table 1 Incidence of Rosettes in the Retinae of Treated Mice

Group	No. of animals treated	Age when killed (d)												No. killed	No. killed	No. killed						
		5		7		10		15		20		30										
		No. killed	0 + + + + +	No. killed	0 + + + + +	No. killed	0 + + + + +	No. killed	0 + + + + +	No. killed	0 + + + + +	No. killed	0 + + + + +	No. killed	0 + + + + +	No. killed	0 + + + + +					
1	47	5	4	1	8	1	1	6	8	1	2	5	6	3	11	2	1	1	7	9	3	6
2	74	9	5	4	11	1	2	8	18	1	17	8	1	1	17	1	2	14	12	1	11	
Control	25	4	4		4	4			4	4		4	4		4	4			5	5		

The animals belonging to group 1 were given three successive doses of cytosine arabinoside (30 mg kg⁻¹). The animals in group 2 were given three successive doses of 50 mg kg⁻¹. +, One to four rosettes; ++, five to ten rosettes; + + +, more than ten rosettes.

The total effect on the retina caused by the administration of cytosine arabinoside to the suckling mouse is summarized in Table 1. Total doses used in this experiment are not very different from those used clinically for the treatment of leukaemia or viral infection. The results therefore indicate the possibility that such treatment may cause lasting damage to the developing retina.

Modulation of Lymphocyte Receptor Redistribution by Concanavalin A, Anti-mitotic Agents and Alterations of pH

VARIOUS lymphocyte surface receptors can be redistributed after cross linkage by external ligands, leading to the formation of patches and caps¹. At 21° C and 37° C concanavalin A (con A) in concentrations greater than 5 µg ml⁻¹ inhibits patch and subsequent cap formation induced by anti-immunoglobulin and other reagents^{2,3}. Con A can also induce cap formation by its own receptors under certain conditions, notably after binding at 4° C^{3,4}. Thus con A has two antagonistic activities in modulating lymphocyte surface receptor distribution and their expression depends on the conditions of incubation. We now report results suggesting that colchicine-binding proteins⁵ (possibly those of the microtubules) are important in the modulation of cell surface mobility. In addition, we have found that alterations of pH affect the ability of lymphocytes to form patches and caps.

Splenic lymphocytes from NCS mice (Rockefeller University) were used. The preparation of fluorescein-labelled con A (fl-con A) has been described elsewhere². Unless otherwise noted, Hanks' balanced salt solution (HBSS) containing 5% (v/v) foetal bovine serum was the medium.

After lymphocytes had been incubated with 100 µg ml⁻¹ fl-anti-immunoglobulin at 37° C for 10 min, about 45% of the total cells were stained and 85% of them showed caps; however, if 100 µg ml⁻¹ con A was added before the fl-anti-immunoglobulin, 45% of cells were stained but only 1%

showed caps. If the cells were pretreated for 1 h at 37° C with 10^{-4} M colchicine, an anti-mitotic agent⁶ which dissociates microtubules⁵, 30% of those exposed to con A and fl-anti-immunoglobulin showed typical patch formation followed by cap formation. Because colchicine did not induce cap formation, it must have partially suppressed the inhibitory effect of con A on patch and cap formation with fl-anti-immunoglobulin (Fig. 1). Similarly, incubation with $100 \mu\text{g ml}^{-1}$ fl-con A at 37° C for 15 min showed that 95% of cells were stained, with only 1–2% showing caps, but 20% or more cap-forming cells were observed when cells were pretreated with 10^{-4} M colchicine.

Fig. 1 Effect of colchicine (a) and vinblastine (b) on inhibition of patch and cap formation by con A. Cells were incubated separately with various concentrations of colchicine and vinblastine at 37° C for 30 min and incubated for another 10 min with $100 \mu\text{g ml}^{-1}$ fl-con A (●) or with $100 \mu\text{g ml}^{-1}$ fl-anti-immunoglobulin in the presence of $100 \mu\text{g ml}^{-1}$ con A (○). Cap formation was determined as described previously³.

Time of incubation with colchicine was not critical, for the drug affected cap formation with fl-con A even if both were added at the same time. Furthermore, when cells were incubated with fl-con A at 37° C for 15 min, washed, and then incubated at 37° C for 1 h in the presence of 10^{-4} M colchicine, 25% of cells formed caps. In contrast, if colchicine was omitted, only about 2% of cells showed caps.

Similar but more marked effects were observed using the *Vinca* alkaloid, vinblastine⁷ (Fig. 1). Other anti-mitotic agents including colcemid, vincristine⁷, and podophyllotoxin⁸ also suppressed the inhibitory effect of con A (Table 1). The relatively weak effect of podophyllotoxin may be related to its impurity as well as its limited solubility in the medium. Griseofulvin⁹ did

not influence the inhibition of patch and cap formation by con A; however, some commercial samples of griseofulvin are reported to lack anti-mitotic activity⁹. Although colchicine, vinblastine and strychnine affect erythrocyte membrane structure⁹, strychnine had no obvious effect in our system. Lumicolchicine¹⁰, a structural isomer of colchicine that does not bind to colchicine-binding proteins and is devoid of anti-mitotic activity, had no effect at concentrations comparable with those used with colchicine (Table 1).

To test the reversibility of the colchicine and vinblastine effects, cells were incubated with each drug at 37° C, washed, incubated for various times at 37° C and tested for cap formation (Fig. 2a). The effect of colchicine persisted for at least 2 h without significant decrease, and even after 6 h, 13% of cells had caps. The colchicine effect therefore seemed to be only partially reversible. In contrast, the vinblastine effect seemed to be almost fully reversible (Fig. 2a). The decrease in the number of cells forming caps with fl-con A after removal of vinblastine was not due to the intrinsic loss of ability to form caps, for there was no decrease in the number of cells forming caps with fl-anti-immunoglobulin during similar periods (Fig. 2b).

Fig. 2 Reversibility of colchicine and vinblastine effects. a, Cells were incubated separately with 10^{-4} M colchicine (●) and 10^{-4} M vinblastine (○) at 37° C for 30 min, washed twice and incubated at 37° C for various times in the medium containing no drug. The cells were subsequently incubated with a, $100 \mu\text{g ml}^{-1}$ fl-con A; b, $100 \mu\text{g ml}^{-1}$ fl-anti-immunoglobulin at 37° C for 10 min.

Table 1 Effect of Anti-mitotic Drugs on the Con A Effect

Drug	Concentration (M)	Caps (%) [*] with fl-con A [†]	Caps (%) [*] with fl-anti-immunoglobulin and con A [‡]
—	0	1 ± 1	1 ± 1
Colchicine	10^{-4}	24 ± 10	30 ± 8
Colcemid	10^{-4}	25	20
Vinblastine	10^{-4}	51 ± 12	51 ± 6
Vincristine	10^{-4}	19	15
Podophyllotoxin	10^{-3}	8	10
Lumicolchicine	5×10^{-4}	3	1
Griseofulvin	10^{-4}	1	2
Strychnine	10^{-3}	4	1

^{*} The percentage of the population showing cap formation was counted using samples of 100 cells or more. In cases where more than ten determinations were carried out, the values are given with standard deviations.

[†] $100 \mu\text{g ml}^{-1}$ fl-con A.

[‡] $100 \mu\text{g ml}^{-1}$ fl-anti-immunoglobulin and $100 \mu\text{g ml}^{-1}$ con A.

Low temperatures¹¹ and high hydrostatic pressures¹² dissociate microtubules. Although our efforts to demonstrate an effect of increased hydrostatic pressures yielded variable results, we found that low temperatures affect the number of cap-forming cells³. If splenic lymphocytes were incubated with $100 \mu\text{g ml}^{-1}$ fl-con A at 4° C, washed in the cold and then incubated at 37° C, approximately twenty times as many cap-forming cells were observed than after incubating cells at 37° C with $100 \mu\text{g ml}^{-1}$ con A. This cannot be explained by the fact that three times as many con A molecules are bound at 37° C than at 4° C, for the differences were observed even when identical numbers of molecules were bound at the two temperatures.

Our results suggest that the integrity of microtubular structures may be required for inhibition of patch formation by con A and that the mobility of cell receptors is modulated by structures associated with or related to microtubules. The concentrations of colchicine and vinblastine effective in our experiments are considerably greater, however, than those required to inhibit mitosis or disrupt microtubular structures visible by electron microscopy⁴. Moreover, microtubules with a diameter of 250 Å have never been observed either in or just under the cell membranes of lymphocytes. It is possible, therefore, that

the system affected by colchicine resembles the 250 Å microtubules but differs from them in organisation. Cationic alkaloids, such as vinblastine or strychnine, can precipitate with actin-like proteins isolated from various cells¹⁴. Although strychnine had no effect in our system, actin-like proteins may form structures that modulate the mobility of lymphocyte receptors. As colchicine, vinblastine, vincristine and podophyllotoxin bind to microtubules^{8,15} and because conditions that disrupt microtubules also affect the inhibition of patch formation by con A, a colchicine-binding protein resembling tubulin seems a more likely candidate than other proteins or phospholipids.

Fig. 3 Effect of pH on patch and cap formation. The following buffered isotonic media were used: 10 mM acetate-buffered saline (pH 4.2, 5.4), 10 mM citrate-phosphate-buffered saline (pH 4.0, 5.2, 5.6, 6.1, 6.4, 7.0), 10 mM Tris-HCl-buffered saline (pH 7.2, 7.6, 8.0, 8.4, 8.8), 10 mM glycine-NaOH-buffered saline (pH 8.5, 8.9, 9.2, 9.6, 9.8), PBS (pH 7.4), HBSS (pH 7.2). Cells were pre-incubated separately in those media at 37° C for 15 min and then incubated with fl-anti-immunoglobulin at 37° C for 10 min in the same media. Cell viability (●) was determined by the trypan blue dye exclusion; bars represent standard deviations of repeated measurements. Cap (○) formation was determined as described previously. The effect on cap formation with fl-anti-immunoglobulin is also shown after prolonged incubation (30 min) of cells in acidic media (●).

The observations reported here may be related to reports that colchicine affects both the agglutination induced by con A and phagocytic events in polymorphonuclear leukocytes^{16,17}, suggesting that the topographical distribution of con A receptors and transport sites for small molecules are controlled by microtubules. The differences we observed in reversibility of the effects of colchicine and vinblastine are similar to those obtained relative to the movement of mouse peripheral macrophages¹⁸.

So far only con A^{2,19}, other mitogenic lectins²⁰ and high concentrations of sugars¹⁹, such as 0.5 M D-mannose, have been shown unequivocally to affect patch formation reversibly. Loor *et al.*¹⁹ reported that LaCl₃ inhibits patch formation induced by anti-immunoglobulin. We could not repeat their experiments because we were unable to prepare 1–10 mM LaCl₃ solutions in media containing phosphate ions at neutral pH without precipitation or lowering of the pH of the medium. Moreover, 10 mM LaCl₃ in 10 mM Tris-HCl-buffered saline (pH 7.0) resulted in cell clumping with a drastic reduction in cell viability and precipitation of fl-anti-immunoglobulin.

We have found that cap formation induced by fl-anti-immunoglobulin was inhibited at both acidic and alkaline pH. A sharp decrease in the number of cap-forming cells was observed at pH 6.1 to 5.2 and neither patch nor cap formation was observed at pH 5.2. When cells were incubated for prolonged periods, the critical pH was more alkaline (Fig. 3). Because slight decreases in cell viability were observed within the effective range (Fig. 3) and the inhibition was reversible (Table 2), the decreases in cap-forming cells in acidic media cannot be accounted for by cell death. Patch formation was frequently observed in alkaline media even in cells not forming caps.

and the absence of caps paralleled the viability curve. It is likely, therefore, that the inhibition of cap formation in alkaline media is due to cell damage and to depression of cellular metabolism before cell death.

Table 2 Effects of Colchicine Treatment and Exposure to Low pH on Cap Formation

First incubation*	Second incubation†	Third incubation‡	I Caps (%) with fl-anti-immunoglobulin	II Caps (%) with fl-anti-immunoglobulin and con A	III Caps (%) with fl-con A
pH 7.2	pH 7.2	pH 7.2	77	2	3
pH 7.2	pH 5.2	pH 7.2	78	2	2
pH 7.2+ colchicine	pH 7.2	pH 7.2	81	39	31
pH 7.2+ colchicine	pH 5.2	pH 7.2	81	41	46

* Cells were incubated at 37° C for 30 min with or without 10⁻⁴ M colchicine and washed.

† Cells were incubated at 37° C for 15 min in citrate-phosphate-buffered saline (pH 5.2).

‡ Cells were incubated at 37° C for 10 min with 100 µg ml⁻¹ fl-anti-immunoglobulin in the absence (column I) or presence (column II) of 100 µg ml⁻¹ con A, or with 100 µg ml⁻¹ fl-con A (column III).

Unlike the inhibition by con A, the effect of acidic pH was not reversed even partially by colchicine. For example, when lymphocytes were treated with 10⁻⁴ M colchicine and subsequently incubated with fl-anti-immunoglobulin in medium at pH 5.2, cap-forming cells were not observed. The lack of effect of colchicine at pH 5.2 cannot be due to the release of molecules from colchicine-binding proteins¹⁵, because the effect was obvious if cells treated with colchicine and then washed were briefly incubated at pH 5.2, and returned to neutral pH (Table 2). The specific mechanism and sites of action mediating the inhibitory effect at acidic pH seemed to be different from those of con A. Patch formation is independent of metabolism^{1,2} and therefore the effects of acidic pH are not attributable to any effects of pH on metabolism. Acidic pH may affect phospholipid head groups of the membrane, the phase separation characteristics of the membrane lipids, or submembranous structures.

Our present and previous data^{20,21} suggest that both the tetravalence of con A and the integrity of a colchicine-binding structure are required for inhibition of patch formation. It is not yet clear whether con A can inhibit micropatch formation demonstrable at the electron microscopic level²² but not at the level of fluorescence microscopy. In any event, our results suggest that although cell receptors may be mobile in the membrane^{23,24} their relative mobility may be modulated by structures the exact nature of which remains to be defined. This hypothesis is compatible with observations²⁵ suggesting that some of the receptors on the cell surface penetrate the membrane possibly to interact with other cellular components.

The SCORAH Automatic Electric all glass WATER STILL (patented)

Automatic Can be left on without attention. Heater current cuts off if water supply is interrupted, or inadequate or forgotten. When receiver (5 litres capacity) is full, current cuts off. When distilled water is drawn from receiver, the still resumes operation until receiver is refilled.

Purity Electrostatically charged condenser droplets can pick up fumes, dust and air-borne organisms from the laboratory atmosphere. The design of the receiver vessel ensures absence of such contamination.

Efficiency Heater of Scorah design and manufacture, consumption 1,700 watts, output 2.4 litres per hour (the full theoretical yield). Cost less than 2p per gallon at 4p per unit.

Safety The heating element is out of contact with the feed water, thus eliminating danger from "live" water supply or electrolytic effects or "burn out".

Assembly No retort stands or clamps are required. The 2½-in. diameter ball joint gives a strainless set-up. Outlet cap on boiler for quick periodical drain-off of sediment. The still may be installed on a shelf or platform about 1 ft. above bench level near a sink and enclosed in a transparent plastic cover to keep out dust.

Heat-resisting glass. Interchangeable ground glass joints.

Crossbands of *Caulobacter crescentus* Stalks serve as Indicators of Cell Age

BACTERIA in the genus *Caulobacter* have a life cycle with two distinct cell types¹: a non-motile mother cell with a stalk extending from one cell pole, and a polarly flagellated swarmer cell which has no stalk. During the life cycle the mother cell elongates and divides to produce a swarmer at its non-stalked pole. The swarmer forms a holdfast at the base of its flagellum and, before division, produces a stalk from the same site. The synthesis of the stalk occurs at the cell-stalk junction².

Structures variously called Querbalken, crossbands, and annuli have been reported in *Caulobacter* stalks since they were first observed in the electron microscope³⁻⁶. This study was undertaken to determine how the formation of these structures is related to the life cycle of the bacterium.

Caulobacter crescentus strain CB2-L was used in all experiments. It was maintained on medium MMB⁷.

In one series of experiments synchronous cultures were initiated with swimmers. *C. crescentus* was inoculated into a sterile, 500 ml, pear-shaped separatory funnel containing MMB and 400 g of 4 mm glass beads. The culture was incubated at room temperature for 24-48 h before the synchrony experiments were begun. Then approximately 4 l of sterile MMB was washed over the beads to remove all unattached or loosely attached cells. The flow was stopped for 15 min to allow swarmer cells to be released by mother cells attached to the beads. Then 150 ml was eluted from the column into a sterile 500 ml Erlenmeyer flask that was transferred to a shaker water bath at 30° C. Ten millilitre samples were collected and fixed with Lugol's iodine at zero time and at 30 min intervals thereafter for examination with the electron microscope (AEI EM6B at 60 kV). Enlarged prints of electron micrographs were used to measure stalk length, cell length, and number of crossbands. Total counts were determined on samples every 15 min using a Petroff-Hauser counting chamber. The curve shown in Fig. 1 was obtained.

The initial population consisted of 5.9×10^6 cells per ml. Oil immersion phase and electron microscopic counts indicated that the swimmers, C_0 , comprised about 90% of the total population (91.5 and 92.5%, respectively). At 30 min some cells

had begun to synthesise stalks but the average stalk length was only 0.10 μ m. At 1 h stalk synthesis had commenced in almost all cells, and the average stalk length was 0.5 μ m. Only one stalked cell in fifty contained a crossband. By 1.5 h the range of stalk lengths was 0.55-1.40 μ m with an average of 1 μ m. About 47% of the stalked cells (twenty-two out of forty-seven) had one crossband (only one in fifty had more). Although many of the cells at 1.5 h had indentations indicating they were in the process of division, most cells separated in the succeeding half hour.

At 2 h, the average stalk length decreased to 0.9 μ m because newly formed swimmers of the next generation, C_1 , had begun to produce stalks. If it is assumed that all C_0 cells had stalks longer than 0.55 μ m (the minimum length observed in these cells at 1.5 h), then 69% (forty out of fifty-eight) had one stalk septation and the average stalk length was 1 μ m, or about the same as at 1.5 h. Therefore the rate of stalk synthesis approached zero at the time of cell division and cell separation.

Fig. 1 Growth of a synchronous culture of *Caulobacter crescentus* CB2-L initiated with swarmer cells. Cells began dividing at about 1.5 h and had completed division by about 2 h. The second doubling was completed by 4 h and the third by 5.5 h.

At 2.5 h stalks of the C_0 population had resumed elongation and the average length was 1.25 μ m. Assuming that the minimum stalk length of these cells increased at the average rate of elongation it would be 0.8 μ m at 2.5 h: 88% of the cells with stalks that length or longer, which are presumably the C_0 population, had a single crossband. Thus, most, if not all, cells of this strain produce a crossband during or shortly after cell division. This conclusion is consistent with the independent studies of Jones and Schmidt⁸.

At 4 h, when the second doubling was completed, nineteen stalked cells had two crossbands and twenty-two had one. This is close to the 1:1 ratio expected if all C_0 cells had developed a second crossband and all C_1 cells had developed their first crossband following division. None of the fifty-two stalked cells examined had more than two crossbands at this time. At 5.5 h, when cell numbers had again doubled, cells with three crossbands were found. By this time, however, the synchrony had deteriorated considerably.

Stalk elongation continued after the first generation so that at 4 h the C_0 cells (those with two crossbands) had an average

stalk length of 1.65 μm and at 5.5 h the average stalk length of the C_0 cells, which now had 3 septa, was 1.75 μm . Apparently, during logarithmic growth, the average rate of stalk synthesis remains high for the first two generations and then decreases. We also noted that stalks with two and three crossbands were much longer (3.15 and 4.91 μm , respectively) during stationary phase than during logarithmic growth, presumably due to the effect of phosphorus limitation known to result in abnormally long stalks in *Caulobacter*².

The following picture of stalk and crossband formation best fits the above data: (1) swarmer cells may begin stalk synthesis any time after division (at one extreme we have an occasional cell undergoing separation having stalks at both exposed ends and, at the other extreme, rare cells dividing without stalks), (2) the rate of stalk synthesis decreases at the time of cell division, (3) crossband formation occurs during division, and (4) stalk elongation resumes after division.

Fig. 2 A *C. crescentus* cell containing eighteen crossbands in its stalk. Most, or perhaps all, cells of this strain form a crossband in their stalks at the time of division so that the minimum age of the cell is eighteen generations.

Using another experimental approach a population of swimmers was grown in conditions of unlimited growth to determine whether crossbands were formed each generation even after numerous divisions had occurred. To accomplish this, swimmers from a logarithmic population were allowed 20–30 min to attach to a short section of sterile glass tubing. The tubing was then aseptically transferred to a siphon connected to a 20 l reservoir of sterile MMB (all at 30° C). The medium was passed through the chamber at a rate of about 40 ml h⁻¹ to remove newly formed swimmers. The section of tubing was removed after 52 h. The cells were fixed and gently dislodged from the wall of the tubing with a transfer loop and observed with the electron microscope. The estimated generation time was 2.7 h. Thus, the predicted maximum age of a cell was nineteen generations. If crossbands were formed each generation, then some cells would be expected to have nineteen crossbands. The maximum number of crossbands found was eighteen, close to the theoretical expectation (Fig. 2).

The results of this study indicate that the stalk of *C. crescentus* CB2-L continues to elongate beyond the first generation and crossbands are formed in most, if not all, cells during the time of division. It seems likely that all caulobacters which produce crossbands (all species in the genera *Caulobacter* and *Asticacaulis*) would produce them in the same manner, so that counting stalk crossbands may become a generally useful procedure for determining cell ages of bacteria in these genera. If so, the effect of cell age upon metabolism and other aspects of cell physiology can be investigated in this group of aquatic bacteria. In addition, it should be possible to follow the ageing of *Caulobacter* communities in their natural habitats.

Histamine H₁ and H₂-Receptors at a Ganglionic Synapse

MANY humoral agents are capable of modulating synaptic transmission in sympathetic ganglia and it has been proposed that a variety of receptors are present at the ganglionic synapse (see Haefely¹). There are thus many possible modulatory mechanisms at this synapse, some of which have a dual nature, the same substance being able both to facilitate and to depress ganglionic transmission by an action on two different populations of receptors. We wish to present evidence that histamine, like the catecholamines² and 5-hydroxytryptamine (serotonin)³, has a dual action at the ganglionic synapse.

Trendelenburg^{4,5} demonstrated that histamine can facilitate transmission through the feline superior cervical ganglion *in vivo* and found that this facilitation could be prevented by the classic anti-histaminic drug, mepyramine⁶. We have observed that histamine can either depress or facilitate transmission in the rabbit superior cervical ganglion depending on circumstances. A dual action of histamine on blood pressure has been reported⁶ and it has been proposed that the pressor effects are due to activation of one type of histamine receptor, the H₁-receptor, while the depressor effects are due to activation of a second type of receptor, the H₂-receptor (J. W. Black, D. A. A. Owen, and E. M. Parsons, unpublished). Whereas H₁-receptors are blocked specifically by mepyramine, H₂-receptors are unaffected by this drug but may be blocked by burimamide (N-methyl-N-(4-(5-imidazolyl)butyl)thiourea)⁷. We wished to establish whether H₁- and H₂-receptors were present at the ganglionic synapse and whether they were responsible for the observed dual actions of histamine.

The action of histamine was investigated on the rabbit isolated superior cervical ganglion in a bath allowing continuous superfusion of the ganglion with Krebs solution at 37° C⁸. Drugs were added to the superfusate either so as to give a constant concentration or by injection of a fixed amount into the superfusion stream. Injections into the superfusion stream are dispersed in a volume of about 10 ml. Stimuli, either submaximal or maximal for eliciting the initial (Sa) component of the postganglionic compound action potential, were delivered to the preganglionic nerve trunk about 30 mm proximal to the ganglion. Postganglionic action potentials were recorded from the internal carotid nerve at least 3 mm distal to the ganglion. Sa amplitude was measured from the pre-existing baseline; in none of the experiments reported here was subdivision of the

Sa component observed. Facilitation or depression is presented in the text as a percentage of estimated control values, allowing for any progressive change in control values with time.

The postganglionic compound action potential evoked by a single stimulus (response elicited at 30 s or, more usually, 1 min intervals) was reduced in amplitude in twelve out of thirteen preparations by histamine acid phosphate given as a constant superfusion ($0.33\text{--}33\text{ }\mu\text{M}$) or by injection of $0.1\text{--}0.33\text{ }\mu\text{mol}$ into the superfusion stream; in only one preparation was the response facilitated by histamine. The mean reduction of responses to maximal stimuli by $3.3\text{ }\mu\text{M}$ histamine ($1\text{ }\mu\text{g ml}^{-1}$) was $14\% \pm 3\%$, $n=8$. The effect of similar concentrations of histamine on action potentials evoked by continuous repetitive stimulation at 2 Hz was less consistent. Repetitive stimulation at this frequency itself induces a substantial facilitation of responses to both submaximal and maximal stimuli as a result of intrinsic modulatory processes⁸; thus, responses to maximal stimuli in these experiments were facilitated by $30\% \pm 3\%$, $n \pm 5$. In contrast to its effect on single responses, histamine depressed the responses to repetitive (2 Hz) stimulation in only one of eleven preparations; in six preparations histamine had no unequivocal effect, while in four preparations a facilitation was observed. In one experiment, $33\text{ }\mu\text{M}$ histamine caused a 29% reduction of responses to single submaximal stimuli (Fig. 1a) and in the same preparation caused a transient 19% facilitation of the responses elicited by stimulation at a frequency of 2 Hz (Fig. 1b).

It seems possible that the facilitatory effect of histamine, sometimes seen when repetitive stimulation was employed, may reflect an action of the drug often masked by its depressant action. Our results suggest that the depressant actions are usually predominant when responses are evoked by single stimuli; with repetitive stimulation, perhaps as a consequence of the activation of intrinsic facilitatory processes, the depressant actions of histamine are less apparent. Mepyramine, the classical antagonist of histamine H_1 -receptors, did not antagonise the histamine-induced depression of responses to single stimuli. On the contrary, in two experiments the depression produced by $3.3\text{ }\mu\text{M}$ histamine was increased in the presence of $2.5\text{ }\mu\text{M}$ mepyramine maleate ($1\text{ }\mu\text{g ml}^{-1}$). In Fig. 2 the histamine-induced depression was increased from 16% to 38% in the presence of mepyramine. In the only experiment in which histamine facilitated responses to single stimuli, the 3–12% facilitation induced by $3.3\text{ }\mu\text{M}$ histamine was replaced by a 22% depression in the presence of mepyramine. On the assumption that the increased depression is due to antagonism by mepyramine of a concomitant facilitatory action of histamine mediated by H_1 -receptors, the characteristics of the depressant action of histamine are best studied in the presence of mepyramine. Other experiments suggested that $2.5\text{ }\mu\text{M}$ mepyramine was adequate for suppression of the facilitatory effects induced by $3.3\text{ }\mu\text{M}$ histamine. In preparations exposed continuously to $2.5\text{ }\mu\text{M}$ mepyramine, the histamine-induced depression of the evoked response was dependent on concentration and the threshold concentration was around $0.03\text{ }\mu\text{M}$. The mean reduction of responses to single stimuli by $3.3\text{ }\mu\text{M}$ histamine in the presence of mepyramine was $25 \pm 6\%$, $n=4$.

If the histamine-induced depression is mediated by H_2 -receptors, this action should be antagonised by the H_2 -receptor antagonist, burimamide. We chose concentrations of burimamide which have been shown to cause significant blockade of H_2 -receptors in the vascular system of the rabbit and on guinea pig isolated atria⁷. In Fig. 2, it can be seen that addition of $4.7\text{ }\mu\text{M}$ burimamide ($1\text{ }\mu\text{g ml}^{-1}$) increased the rate at which recovery from the histamine-induced depression occurred after removal of histamine from the superfusion medium. Further, a subsequent superfusion with $3.3\text{ }\mu\text{M}$ histamine in the presence of both mepyramine and burimamide ($4.7\text{ }\mu\text{M}$) caused a much smaller depression (17%) of the evoked response; increasing the burimamide concentration to $47\text{ }\mu\text{M}$ almost abolished the depressant action of histamine in this experiment. In three out of five experiments, a combination of $2.5\text{ }\mu\text{M}$ mepyramine and

Fig. 1 Effect of histamine on amplitude of postganglionic compound action potential evoked by a single submaximal stimulus (a) or by repetitive submaximal stimulation at 2 Hz (b). Histamine ($33\text{ }\mu\text{M}$) present in perfusion medium for periods indicated by the black bars. In (a) each point represents a single observation or the mean of two or three observations. In (b) each point is the mean $\pm$ s.e.m.

$47\text{ }\mu\text{M}$ burimamide completely abolished the effects of $3.3\text{ }\mu\text{M}$ histamine on responses to single stimuli; in the other two preparations a residual histamine-induced depression of about 3% remained. The presence of both blockers also completely abolished the actions of $0.1\text{ }\mu\text{mol}$ ($30\text{ }\mu\text{g}$) histamine injections into the superfusion stream.

In the absence of mepyramine, $47\text{ }\mu\text{M}$ burimamide consistently antagonised the depressant action of histamine and revealed the facilitatory action. In the experiment shown in Fig. 3, $3.3\text{ }\mu\text{M}$ histamine induced a 16% depression of the evoked response on initial superfusion and a 17% depression on a second superfusion. Burimamide ($47\text{ }\mu\text{M}$) accelerated the recovery from this second histamine-induced depression, and a third exposure to histamine in the presence of burimamide resulted in a 10% facilitation of the evoked response. The subsequent addition of $2.5\text{ }\mu\text{M}$ mepyramine to the superfusion medium completely abolished this facilitation, only a small depressant action being apparent on a fourth superfusion with histamine. In each of four experiments superfusion with $3.3\text{ }\mu\text{M}$ histamine in the presence of burimamide produced a facilitation ($10\% \pm 1\%$).

If the lack of effect of histamine on many preparations stimulated at 2 Hz is due to approximately equal facilitatory H_1 - and depressant H_2 -actions, then blockade of one type of receptor should reveal the action mediated by the other. This was the case: one preparation, which initially failed to respond to injections of $0.1\text{ }\mu\text{mol}$ histamine, responded with 7–8% facilitation of the evoked action potentials in the presence of $47\text{ }\mu\text{M}$ burimamide; in another preparation, $2.5\text{ }\mu\text{M}$ mepyramine revealed a small (4–5%) histamine-induced depression to injections of $0.1\text{ }\mu\text{mol}$.

Neither mepyramine nor burimamide in the concentrations studied here had any detectable effect by themselves on the

amplitude of the postganglionic compound action potential. In some experiments (see, for example, Fig. 3), long-term fluctuations in action potential amplitude occurred, but these appeared to be unrelated to the addition of drugs.

On the assumption that mepyramine and burimamide are relatively specific antagonists of H_1 - and H_2 -histamine receptors⁷ respectively, the above results are consistent with the presence at the ganglionic synapse of both these receptor types, H_1 -receptors mediating the facilitatory actions of histamine and H_2 -receptors mediating the depressant actions. It is interesting that a recent report⁸ has suggested that there are two sorts of 5-hydroxytryptamine receptors at the ganglionic synapse, one mediating a depressant, the other an excitatory action. The localisation of the histamine receptors either presynaptically or postsynaptically is not possible on the available evidence, although it is known that histamine causes little or no measurable depolarisation of ganglion cells (ref. 1; and D. I. Wallis and B. Woodward, unpublished). The presence at the ganglionic synapse not only of H_1 - and H_2 -histamine receptors, but also of α and β adrenoreceptors², muscarinic acetylcholine receptors, tryptamine receptors^{3,9}, γ -aminobutyric acid receptors^{10,11}, and receptors to certain polypeptides¹ is extremely puzzling. Are all these receptors merely vestigial? Do they perhaps represent an inevitable but physiologically insignificant sensitivity of the mechanisms operating at the synapse to biologically active substances or are they, on the other hand, involved in a complex

Fig. 2 The effects of mepyramine and of a combination of mepyramine and burimamide on the depressant action of histamine. Responses to single maximal stimuli. Role of Insulin as a 'Permissive' Hormone in Mammary Gland Development

THE growth and differentiation of the mammary gland is controlled by the synergistic action of insulin, prolactin and ovarian or corticosteroid hormones¹⁻⁴. The ovarian steroid induced alveolar development of the virgin mammary gland *in vivo* is mediated by activation of nucleic acid and protein synthesis⁵⁻⁹ and mitosis⁸⁻⁹. On the other hand, numerous studies using organ cultures, mostly of fragments of mid-pregnant mammary gland, emphasised the role of insulin as the mitogenic hormone in mammary gland development¹⁰⁻¹². This variable nature of responsiveness of the mammary tissue to hormones *in vivo* and in organ culture has been discussed in recent reports^{13,14}. The proliferative mammary gland of pregnancy, mostly used in these organ culture studies¹⁰⁻¹², should contain a large proportion of cells in the division cycle at the time of excision; we considered that hormonal regulation of the fate of these dividing cells during incubation *in vitro* may influence the interpretation of the results obtained from the organ culture studies. In order to test this possibility, mid-pregnant mammary cells of Balb/c mice were labelled for 1 h with ³H-thymidine (³H-dT) *in vivo*, and the transit patterns of the labelled cells reaching mitosis were determined at different times in organ culture.

Fig. 1 Number of ³H-dT labelled mitoses per 1,000 mammary epithelial cells at different times in organ culture. The mammary gland of a 13-d-pregnant Balb/c mouse was used. Days of pregnancy were determined by the vaginal plug method. 100 μ Ci ³H-dT (49.2 Ci mmol⁻¹) (New England Nuclear Corporation, Boston, Mass.) was injected intraperitoneally 1 h before killing by cervical dislocation. Pulse labelling time of ³H-dT in mouse mammary gland *in vivo* is 30 min¹⁵. For organ culture, fragments (1-2 mm) of mammary gland were incubated at 37°C in 95% O₂ and 5% CO₂ atmosphere in plastic Petri dishes containing Waymouth (MB 752/1) medium with penicillin⁶. The organ culture medium was supplemented with 5 μ g ml⁻¹ each of insulin (▲), or insulin + prolactin (●), or prolactin (■) or was unsupplemented (○). The cultures were terminated at different times and the explants were fixed in acetic acid and ethanol (1:3 v/v) for liquid emulsion autoradiography (Kodak NTB 2)⁴. The autoradiograms of histological sections were scored under a 100 $\times$ oil immersion objective. The data represent typical values of 3-4 sets of cultures and at each time point 5,000 cells from 4-5 explants were scored. Metaphase to telophase cells were counted as mitosis.

As expected, mammary epithelial cells were initially labelled at a high frequency. The average number of silver grains per nucleus was reduced at different times of incubation, suggesting that the slight initial increase in the frequency of labelling is due to the mitotic division of some of the labelled cells rather than to continued incorporation of ³H-dT during incubation. Figure 1 shows that in I medium and in P containing insulin or prolactin alone the frequency of labelled mitoses increased modestly at 6 h, then decreased to zero, whereas in IP medium the frequency of labelled mitoses increased more than seven-fold at

6 h, decreased until 48 h, and rose again at 72 h. In NH medium, the frequency of labelled mitoses after an initial rise decreased to zero at 24 h; both in P and in NH medium extensive alveolar degeneration also occurred at this time. These results show that the mammary cells which were in the progenitor compartment *in vivo* can continue through the cell cycle reaching mitosis in organ culture. The variations in the frequency of labelled cells reaching mitosis in I, IP, or P medium at different times indicate, however, that the hormones greatly influence the cell transit time in organ culture.

Fig. 2 Percentage of ³H-dT labelled mitoses among the mitotic cells. 100-200 cells were scored at each time point. ▲, Insulin; ○, prolactin; ●, insulin + prolactin. Other details as in Fig. 1.

In I medium the proportion of mitoses which are labelled increased slowly during the initial 24 h in organ culture, whereas in P and IP medium the proportion of labelled mitoses reached nearly 100% at 6 h, then dropped to zero at 48 h; in IP medium it rose again at 72 h (Fig. 2). The slow rate of increase of labelled mitoses between 6 h and 24 h in I medium strongly suggests that cells which were in the S phase *in vivo* spend a long time completing DNA synthesis *in vitro*, presumably because of a delayed recovery from the initial lag period in organ culture. The near 100% proportion of labelled mitoses at 6 h (7 h after injection of ³H-dT) in IP medium shows that mammary cells in IP medium complete DNA synthesis at a nearly normal rate (the duration of S in mid-pregnant mammary cells being 8-9 h (ref. 16)) reaching mitosis after a short initial latent period in organ culture. The unusually long S phase (20-21 h) (refs 15 and 16) of virgin mammary cells should similarly cause DNA synthesis to continue for an extended period during the recovery from the initial lag and this, rather than the earlier suggestion that virgin mammary cells acquire a delayed sensitivity to insulin in organ culture¹⁷, may be the explanation of the late rise of DNA synthesis in these cells in I medium.

Figure 3 shows that in I medium total mitosis slightly increased at 24 h but that it was below the initial value. In IP medium, a modest increase of mitosis at 6 h was followed by a two-fold rise at 12 h, a decrease to nearly zero at 48 h and another increase at 72 h. In P medium the general pattern was similar to that in I medium, but the mitotic activity was slightly higher than in the I medium until 24 h, and at 48 h it dropped to zero. In NH medium the cells failed to recover from the initial lag period and the mitotic activity declined to zero at 24 h. Since in I medium 65-75% of mitoses were labelled during the interval between 6 and 24 h (Fig. 2), the only slightly increased mitotic activity during this period indicates a negligible stimulation of new cells into mitosis by insulin in organ culture. In IP medium, since only 12% of mitoses were labelled at 24 h (Fig. 2), 88% of the cells in mitosis observed at this time must have been initiated into the division cycle during organ culture. Results in Fig. 3 further show that the addition of prolactin after 24 h incubation in insulin alone stimulated new cells into mitosis.

Fig. 3 Total mitotic (labelled and unlabelled) activity in mammary epithelium of mouse mammary gland in organ culture. ○, Insulin; ●, insulin + prolactin; ■, prolactin; ▲, no hormone; □, insulin 24 h, then insulin + prolactin up to 30 h. Arrow indicates the time prolactin was added. Other details are as in Fig. 1.

These observations thus show that under the conditions of the previous studies¹⁸⁻²⁰ mid-pregnant mammary cells which were in the division cycle *in vivo* should show increasing levels of ³H-dT incorporation (after 3-6 h pulse labelling *in vitro*) up to 24 h during their recovery from the lag period in I medium, which may lead to the interpretation that insulin alone stimulated DNA synthesis and mitosis in the mammary epithelial cells in organ culture^{11,12}. Our results suggest, however, that the cells which divide in the mammary tissue during the early hours of insulin-supplemented organ culture are mostly those which had already begun the division cycle in the mid-pregnant mammary gland *in vivo*. Insulin alone does not initiate new cells into proliferation, but acts as a 'permissive hormone'²¹ supporting completion of the division cycles of those cells which were initiated *in vivo*. The permissive action of insulin is, however, obligatory for the mitogenic action of prolactin in organ culture of mouse mammary tissue. Since exogenous ovarian steroids are detectable in the mammary tissue 72 h after a single injection²² the mitogenic action of insulin plus prolactin may be synergistic with the endogenous ovarian hormones carried in the mid-pregnant mammary tissue in organ culture. Contrary to earlier suggestions^{11,12} the requirement of hormones for mouse mammary cell proliferation may not be different *in vivo* and in organ culture.

Divinyl Ether-Maleic Anhydride (Pyran) Copolymer used to demonstrate the Effect of Molecular Weight on Biological Activity

DIVINYL ether and maleic anhydride form a 1:2 copolymer, which is reported to have the structure shown here¹. It is commonly known as pyran copolymer, although we prefer to call it DIVEMA, an acronym for divinyl ethermaleic anhydride. It has been designated as NSC 46015 by the National Cancer Institute.

The copolymer has various biological activities and has elicited considerable interest, as demonstrated by more than forty articles since 1967. DIVEMA has activity against several solid tumours, for example, adenocarcinoma 755², Lewis lung carcinoma³, C3H mouse mammary tumour³, and has been approved for initial clinical evaluation. It induces interferon⁴; it is active against several viruses, including Friend leukaemia^{5,6}, Rauscher leukaemia⁶, Moloney sarcoma⁷, vesicular stomatitis⁸, Mengo⁹, MM¹⁰ and foot-and-mouth disease¹¹; it has antibacterial¹² and antifungal activity^{12,13}; it stimulates immune response¹⁴⁻¹⁷; it inhibits adjuvant disease¹⁸, and it is an interesting anticoagulant¹⁹.

Several observations led us to a more thorough investigation of the structure of DIVEMA. Degraded material was found to have considerably lower acute toxicity in mice. Although most of a polymer prepared with ¹⁴C-labelled maleic anhydride was excreted by mice fairly rapidly, a portion was excreted very slowly²⁰. Munson *et al.*²¹ had shown a biphasic response of the reticuloendothelial system (RES) towards DIVEMA; initially there was a decrease in the rate of phagocytosis, followed by a considerable increase over the control after several days. Combining these observations, we hypothesised that the copolymer might consist of two materials, one toxic, very slowly metabolised, and responsible for the RES depression, and the other less

toxic, rapidly metabolised, and responsible for the RES stimulation. We assumed that the two materials would differ only in molecular weight, and that the high molecular weight portion was the undesirable material. This has now been confirmed.

To characterise the polymers, they were converted into their methyl esters by first refluxing them in methanol and then treating them with ethereal diazomethane. These esters were fractionated by gel permeation chromatography (GPC) on a Styragel column using tetrahydrofuran (THF) as solvent (similar results have been reported by Butler and Wu²⁰). A comparison of the molecular weights of the anhydride and the methyl ester demonstrated that no appreciable degradation had occurred during esterification. The intrinsic viscosities and weight-average molecular weights of fractions from a preparative GPC were determined in THF. They were then analysed on an analytical GPC column and compared with known polystyrene standards on the same column using the same solvent. A plot of the peak-elution volumes against $\bar{M}_w[\eta]$ gave a single curve (Fig. 1), $\bar{M}_w[\eta]$ being the 'universal parameter'²³. We were then able to determine the molecular weights and the polydispersities of other samples by using this calibration curve. This procedure demonstrated that the usual slurry polymerisation to high conversion²⁴ leads to polymer with broad molecular weight distribution.

Our goal was the synthesis of polymers in the desired molecular weight range with a narrow distribution, since we felt that the high molecular weight portion which would be present if the distribution were broad would contribute more to toxicity than to activity. In an attempt to obtain sufficient sample for evaluation, several large-scale fractionations of anhydride were carried out on sand columns, using a procedure developed originally for the fractionation of polyolefins²⁵. Because it was difficult to obtain enough material for evaluation by fractionation, we turned to direct polymerisation. By low-temperature photochemically initiated solution polymerisation in THF, a solvent for the copolymer at low but not high temperatures, narrow distribution copolymer could be prepared; molecular weight could be controlled to some extent by varying the monomer con-

Fig. 1 Universal calibration curve for GPC using THF at 30°C. The line represents polystyrene standards, the circles pyran copolymer methyl ester fractions.

centrations. Acetone was a better solvent for the copolymer and almost any desired molecular weight could be obtained using a free-radical initiator in acetone with THF as a chain-transfer agent.

Table 1 lists different polymers in order of increasing molecular weight ($\bar{M}_p$ is the peak molecular weight from GPC of the methyl esters). NSC 46015 is a sample approved for clinical evaluation and XA 124-177 is a similar slurry polymer of higher molecular weight; both have broader molecular weight distributions than either the fractionated polymers or those made in solution. Even though the differences in acute toxicity are not large, it is apparent that

toxicity as measured by the other criteria increased with increasing molecular weight. Thus, SGPT levels and inhibition of drug metabolism, both measures of liver function, increase with increasing polymer size, as does sensitisation to endotoxin. Phagocytosis is stimulated by low molecular weight polymer and depressed by high.

Most important, it was demonstrated that low molecular weight copolymers with narrow molecular weight distributions are not only low in toxicity but retain the antitumour activity shown by higher molecular weight samples against both Ehrlich adenocarcinoma and Lewis lung carcinoma in mice; the latter has proved extremely difficult to inhibit with standard chemotherapeutic agents^{26,27}.

Data available on the relationship between molecular weight and antiviral activity are limited to encephalomyocarditis in mice. The only conclusion which can be drawn at present is that with this virus a higher molecular weight is required for activity than for antitumour activity. Obviously other viruses must be examined before generalisations can be made.

In the light of the numerous literature references²⁸ to problems associated with the toxicity of pyran copolymer, the synthesis of materials with lower toxicity could be of major importance.

We thank Drs A. E. Munson and W. Regelson, Medical College of Virginia, Richmond, for most of the biological data; details of these tests will be published by them. We also thank S. J. Keahey, Mr R. J. Kridler, Dr L. G. Bunville, Mr O. W. Marks and Dr R. J. Samuels for fractionations and physical data.

Hyperthermia in Rabbits from Injection of Malaria Infected Erythrocytes in the Pre-optic Area

MALARIA, when introduced naturally by the bite of an anopheline mosquito, goes through an exoerythrocytic stage in the parenchymal cells of the liver. Here the malarial parasite matures to a mature merozoite that infects erythrocytes. When the parasite has multiplied, the red blood cell bursts and many new infective merozoites are released. These infect new erythrocytes. During lysis of erythrocytes the host develops a fever¹. It is not known whether the malarial parasite produces a pyrogen, like bacteria, or whether the malarial fever results from destruction of red blood cells.

The pre-optic area of the brain of mammals is thought to be the site of both temperature reception and integration in the central nervous system²⁻⁴. This area is far more sensitive to injected pyrogens than other sites in the brain⁵ suggesting that pyrogens interfere directly with nervous regulation of body temperature. Substantial fevers can be produced in mammals by injecting 1/100 of the effective intravenous dose of pyrogen directly into the pre-optic area⁶. Pyrogens released from leukocytes during infection are thought to be responsible for biogenic fevers, whereas pyrogens released from bacteria are scavenged from the blood and do not reach central nervous sites of temperature regulation⁶. When injected directly into the brain both classes of pyrogens induce fever, but leukocytic pyrogen acts more quickly (8 min) than bacterial pyrogens (45 to 60 min)^{4,5}. We took advantage of this differential sensitivity to test the pyrogenicity and nature of malarial parasites.

Rabbits, anaesthetized with chlorpromazine (25 mg kg⁻¹) followed by sodium pentobarbital (20 mg kg⁻¹), were implanted with cannulae (David Kopf) consisting of a twenty-two gauge needle mounted on stainless steel tube 4 mm in diameter with threads cut on outside and inside. The inside holds a set screw to retain a neoprene seal. The threads on the outside enable the cannula to be screwed directly to the skull. The cannula was further secured by acrylic powder mixed with methylmethacrylate solvent. One week after insertion of the cannula, the rabbit was used for the experiment. Test materials were injected using a Hamilton 50 μ l syringe with an attachment to deliver 1 μ l at a time. The rabbit's rectal and ear skin temperatures were taken with copper constantan thermocouples and recorded by a Honeywell recording potentiometer. The rabbit was placed in a restrainer for 30 min before injection.

Four materials were injected into the test rabbits. To determine if the cannula was correctly placed, 'Piromen' (Travenol Laboratories, Morton Grove, Illinois), a *Pseudomonas* polysaccharide complex pyrogen, was injected. If the rabbit showed a fever, approximately 1° C rise, within 1 h of receiving 3 μ l of 'Piromen' (50 μ g ml⁻¹) it was used in the experiment. Rabbits were injected with an injectable grade saline solution containing 1% benzyl alcohol (Lilly) to determine if the cannula was clear of bacterial pyrogen and if the injection itself was responsible for the fever. As a control on leukocytic malarial-independent pyrogen, non-infected red blood cells were also injected. Malarial parasites and blood cells were obtained from female ICR white mice. The malaria parasite *Plasmodium berghei* strain NK65DA was transferred by intraperitoneal injection.

The level of parasitaemia was monitored by microscopically examining blood samples stained with Giemsa blood stain.

The blood of both the control and the infected mice was prepared in the same way. The mouse was anaesthetized with ether and the thoracic cavity opened. Heparin solution (0.1 ml), made by adding 0.1 ml of heparin (1,000 USP units ml⁻¹) to 2 ml of saline, was injected intraventricularly. The right lung was then removed and the blood was taken from the thoracic cavity and placed with 0.5 ml of heparin solution. The blood was then centrifuged at 1,000g for 10 min. The plasma and buffy coat supernatant (leukocytes)⁷ were discarded. The

Fig. 1 Direct febrile response to malarial plasmodia. Changes in body temperature and ear temperature of a rabbit following microinjection into pre-optic/anterior hypothalamus. *a*, Saline control; *b*, non-infected RBC; *c*, 'Piromen'; *d*, infected RBC. Arrows indicate time of two injections of 2 μ l in *a*, *b*, and *d*, and of a single injection of 3 μ l in *c*. Saline and washed RBC from mice caused no changes in temperature (*a*, *b*). Bacterial pyrogen, 'Piromen', caused elevation of body temperature to febrile level more than 1 h after injection (*c*). Injection of malarially infected mouse RBC (*d*) causes elevation of body temperature over 1 h after injection. Elevation of body temperature is accompanied by marked decrease in ear temperature indicating vasoconstriction to conserve heat. Ear vessels dilate after 3.5 h as the body temperature stabilizes at febrile level.

packed red blood cells were resuspended with 2 ml of saline of the type mentioned before. The process was repeated four times. The last time the packed red blood cells were suspended in only 0.5 ml of saline and used for injection. The red blood cells were kept in an ice bath at all times except during centrifugation.

Both body temperature and ear skin temperature were within an expected normal range following the injection of saline into the pre-optic region of the rabbit (Fig. 1*a*). Normal mouse red blood cells caused only small fluctuations in ear and rectal temperatures. When the rabbit received malarial infected mouse red blood cells, the rectal temperature rose 1.5°C, and the ear skin temperature fell below 34°C, presumably due to

vasoconstriction in the ear to conserve body heat. The same set of materials, but in varying order, were injected two or three times in each of three rabbits with the same result, no change in body or ear temperature on receiving repeated doses of saline and washed normal mouse RBC, but increased body temperatures of 1.5 to 3°C and reduced ear temperature on receiving infected mouse blood cells or 'Piromen'.

Our results indicate that the presence of the malarial parasite is necessary for fever. The parasite may produce a pyrogen or induce the red blood cell to produce pyrogen. The malarial pyrogen differs from leukocytic pyrogen because the latency of the induced malarial fever is more than 1 h but the latency of the fever induced by a leukocytic pyrogen is about 10 min⁸. The timing and magnitude of the fever from malarial pyrogen resemble the response to the bacterial pyrogen, 'Piromen'. The malarial parasite, however, is a protozoan and eukaryotic and it lacks a cell wall, which is involved in production of bacterial pyrogen⁸. The chemical nature of the malarial pyrogen is unknown, but may differ from the classical division of natural pyrogens into leukocytic or bacterial.

Our studies do not distinguish whether natural malarial fever resulting from lysed red blood cells and plasmodium in the blood activating a leukocytic pyrogen⁹ or a pyrogen produced directly by the parasite is responsible for the fever. In the latter case, malarial fever might differ from the bacterially induced fever. Further characterization of the pyrogen associated with malarially infected red blood cells may yield a product useful for the study of temperature regulation and mechanisms of fever, as well as suggest new clinical procedures for dealing with malarial fever.

This work was supported in part by a National Science Foundation grant. We thank Dr P. Silverman and Dr N. Alger for advice and access to cultures of *Plasmodium berghei* strain NK65DA.

Kidney Graft Survival and Matching for HL-A and ABO Antigens

THIS preliminary report considers 126 kidney transplants from cadaver donors performed in one centre over a period of 6 yr. All were first grafts. Previous sensitisation to human leukocyte antigens (HL-A) had been kept to a minimum by avoidance of transfusion where possible.

Fig. 1 Actuarial curves of group O and non group O kidney recipients showing total graft failure rate.

Eight patients had weak lymphocytotoxic antibody induced by pregnancy or transfusion before transplantation.

The criterion used for a successful graft at any one time was a kidney supporting life. Rejection was assessed histologically on allograft kidneys, removed surgically or at autopsy, without knowledge of the degree of matching.

Actuarial curves¹ were computed for three, monthly periods using rejection as the criterion of failure. Those kidneys or patients that were lost for reasons other than rejection as assessed by clinical and laboratory examination (as, for example, haemorrhage, ureteric fistula or infection) were censored. Their survival was included in the actuarial curves while they were functioning, but their failure did not contribute to the percentage failure due to rejection. The numbers on the curves represent the number of individuals entering the previous three monthly period.

The HL-A antigens of donors and recipients were assessed at the time of transplantation, and also retrospectively on lymphocytes which had been stored in liquid nitrogen. A panel of well authenticated "monospecific" antisera was used. Many antisera were derived from the IVth International Histocompatibility Workshop. Specificities tested for were: HL-A1, HL-A2, HL-A3, HL-A9, HL-A10, HL-A11, W19, W28 HL-A5, HL-A7, HL-A8, HL-A12, HL-A13, W5, W10, W14, W15, W16, W17, W18, W21, W22, W27. For all except W16 and W21, several sera were used to determine each specificity.

In our study the basic assumptions underlying transplantation practice have been questioned. It is usually accepted that the rules applicable to blood transfusion in relation to the ABO groups also apply to transplantation of the kidney, namely when these rules are contravened, immediate (hyperacute) rejection usually supervenes. It seemed worthwhile, however, to examine whether those ABO categories, regarded as compatible for blood transfusion purposes, also behaved as compatible in organ transplantation. The O allele is believed to produce no antigen on erythrocytes, but it might form an immunogen on tissue cells.

The actuarial curves for the survival of group O recipients (who received kidneys only from group O donors) and non group O recipients of group A, B or AB (who received kidneys from ABO compatible donors) were compared for all graft failures and for failure attributable to rejection (Figs 1 and 2). The survival of group O recipients was better than that for non group O recipients. Rejection failure and survival, when assessed at specific periods, were not significantly different between the two groups. Using the regression method for life tables², however, which assesses differences between the groups over the whole time scale, the log-likelihood ratio is 1.99 ($P < 0.05$).

This suggests that the difference between the survival of group O and non group O recipients is real. The relatively

small number of grafts makes statistical significance difficult to obtain, but a previous series of forty-three grafts performed before HL-A typing was available shows the same trend of superior long term survival of group O recipients. The preferential survival of group O recipients, if real, might be due either to lower immunocompetence of group O individuals to antigens effective in eliciting graft rejection, or to an adverse effect of an incompatibility of the ABO system or an antigen linked with it. The incompatibility, for example, might conceivably be "antigen O" itself, and so a better survival might be expected in the category "donor A to recipient A" than in category "donor O to recipient A". Actuarial curves showed a slightly better survival for the donor A to recipient A group but this was not statistically significant.

We attempted to determine if group O individuals were less capable of responding to HL-A antigens than individuals of other groups. The ABO groups of ninety-four multiparous women who had developed cytotoxic antibody showed no disturbance from expectation. It seems therefore, that antibody produced to HL-A antigens by this immunisation route is not less in group O than in individuals of other groups.

In initial studies with the whole data on first grafts from cadaver donors, the influence of compatibility of the HL-A antigens seemed dubious. There seemed to be an increased survival rate for HL-A identity, but with the small numbers available this did not reach statistical significance.

In group O recipients there were no instances of failure due to rejection, after 9 months, and incompatibilities of HL-A antigens of either the first or second segregant series seemed to have no significant effect on survival.

In non group O recipients there was no significant relationship between rejection and incompatibilities at the first segregant series. A significant relationship did, however, exist between the number of incompatibilities at the second segregant series and rejection in this group (Fig. 3). Grafts having no incompatibilities at the second segregant series survive best, those having two incompatibilities the worst, and those with one incompatibility are intermediate ($P < 0.05$, using the regression method). This reinforces the observation³ that compatibility of the second segregant series is more important than of the first.

Our data suggest that for first grafts, loss of allografts by rejection is less in group O than in other groups, and that for the non group O recipients, matching at the second segregant series produces improved survival. Work in progress indicates that a different picture is presented by second grafts. If confirmed, these trends could make organ donor-recipient matching easier.

We thank Professor R. Y. Calne for making his patients available for this study and the Medical Research Council for grants to V. C. J. and J. H. R.

Fig. 2 Actuarial curves of group O and non group O kidney recipients showing failure rates due to rejection ($P < 0.05$).

Fig. 3 Actuarial curves of non group O kidney recipients (that is, groups A, B or AB) showing failure rates due to rejection in recipients receiving kidneys with 0, 1, or 2 HL-A incompatibilities at the second segregant series.

We acknowledge antisera donated by the laboratories of origin and the National Institutes of Health, USA, and the National Organ Matching Service.

Effect of Sodium Fluoride on Regeneration in the Rabbit Ear

THE unique example of adult mammalian tissue regeneration seen in the rabbit's ear after removal of 1 cm² of its whole thickness¹ has been used to investigate the effects of procedures such as the administration of steroids on this regeneration²⁻⁵.

Sodium fluoride is known to be an enzyme inhibitor⁶⁻⁸ and apparently interferes with carbohydrate metabolism^{9,10} and inhibits cell growth¹¹. The effects of sodium fluoride on regeneration in the rabbit's ear could not, however, be anticipated from the results of these mainly *in vitro* studies. There is contradictory evidence regarding the effects of sodium fluoride on the inflammatory process. It has been suggested that this process, if occurring, is enhanced^{12,13} or reduced¹⁴. The inflammatory process may be an essential precursor to regeneration by the release of a substance or substances necessary for initiating regeneration.

Three groups of mature male rabbits were used: eighteen controls which received London tap water containing 0.3 p.p.m. sodium fluoride; a group of six which received drinking water containing 150 p.p.m. sodium fluoride; and a group of five which received drinking water containing 10 p.p.m. sodium fluoride. All rabbits were anaesthetised with intravenous pentobarbitone, and a hole 1 cm² in area was punched through the whole thickness of each ear with a special punch. Photographs of the ventral surfaces of the ears immediately after the operation (0 d) and at intervals of 7 d up to 49 d were taken with a cm ruler placed alongside the defect. The growth of the regenerated tissue was measured in terms of surface area using the method previously described¹⁵. The regenerated tissue was expressed as a percentage of the initial defect. Any reduction in the size of the hole due to contracture was excluded.

Fig. 1 Comparison of rates of growth at 7 d intervals: ○—○, controls; ■—■, rabbits receiving drinking water containing 10 p.p.m. sodium fluoride; ●—●, rabbits receiving drinking water containing 150 p.p.m. sodium fluoride.

Figure 1 shows the means of the new growth of tissue as a percentage of the original defect in the three groups at 14, 21, 28, 35, 42 and 49 d and Table 1 gives the means and standard errors of the means of the new growth at the same intervals. At 14 d there was a highly significant increase in regeneration in the two groups receiving sodium fluoride as compared with the controls at 14 d ($P < 0.005$). At 21 d the differences were still significant (for the group receiving 150 p.p.m. sodium fluoride $P = 0.001$ to 0.005 and for the group receiving 10 p.p.m. $P = 0.01$ to 0.02). At 28 d the 150 p.p.m. group still showed a significant increase in regeneration compared with the controls ($P = 0.02$ to 0.025) but in the 10 p.p.m. group regeneration was not significantly different from the control group. At 35, 42 and 49 d there was no significant difference between the three groups. (The difference between the 10 p.p.m. group and the control at 49 d was not significant: $P > 0.05$.) In the controls at 49 d, contraction caused about 3% of the reduction in the size of the hole, but in the animals receiving sodium fluoride contraction contributed much more (about 20%) to the decrease in the size of the hole. It should be emphasised that the technique used in this experiment measured only regenerated tissue. Figure 2 illustrates the marked difference in the amount of regenerated tissue seen at 14 d in the control (a) compared with the regeneration in an animal drinking water containing 150 p.p.m. sodium fluoride (b).

These results indicate that sodium fluoride in the doses administered produces a marked acceleration in regeneration

Table 1 Areas of New Growth as Percentages of Initial Defect at Weekly Intervals

Group	No. of rabbits	Mean areas of new growth $\pm$ s.e.					
		Time after excision (d)					
		14	21	28	35	42	49
Controls	18	22.3 ± 3.5	49.1 ± 2.4	63.9 ± 2.8	72.8 ± 2.5	77.0 ± 2.8	85.2 ± 2.6

during the first three or four weeks following the whole thickness removal of 1 cm² of the rabbit's ear. It is difficult to state how sodium fluoride affects the process of regeneration since the factor or factors stimulating regeneration are not known. Present investigations suggest that at least four enzymes (acid phosphatase, alkaline phosphatase, non-specific esterase and cytochrome oxidase) are not reduced in the region of the blastema although these enzymes are reported to be inhibited by fluoride^{6-8,16}. Regeneration may be stimulated by a wound hormone produced by cell damage following injury and sodium fluoride may increase this early cell damage with the result that the stimulus to regeneration is enhanced. Preliminary investigations suggest that this is the case since there appears to be an increase in the acid phosphatase present 2 d after operation in the fluoride-treated animals as compared with control animals at the same stage. This could be due to increased lysosomal breakdown stimulated by the presence of sodium fluoride.

We thank the MRC for support and also Mr Kevin Fitzpatrick and Mr Paul Bates for assistance with the photography.

Isomerisation of the Visual Chromophore All-trans to 11-cis Retinal

It is well known¹ that the only action of light in vision is the photoisomerisation of the 11-cis retinylidene (derived from vitamin A aldehyde) prosthetic or chromophoric group of rhodopsin, from the 11-cis to the all-trans configuration. After several poorly understood intermediate steps rhodopsin is bleached to opsin, retinal being set free in the all-trans form. Two paths are now possible for the all-trans retinal: either isomerisation to the 11-cis configuration and joining with opsin to form rhodopsin (the situation here, however, is not clear and is likely to be rather complex^{2,3}), or reduction to retinol (vitamin A) and, after esterification, storage as the 11-cis ester⁴.

Since there are six known isomers of retinal, namely all-trans, 9-cis, 11-cis, 13-cis, 9-13 dicis, and 11-13 dicis, the specific isomerization of the all-trans to the 11-cis configuration and the large amounts of the 11-cis form present in the eye⁴ have long been an enigma. Indeed Wald¹ has asked "why should three phyla independently have selected for vision such a fundamentally improbably, hindered cis configuration of retinal (as the 11-cis configuration)?"

In the course of developing a method for simulating *ab initio* molecular-orbital calculations⁵ we have studied all-trans retinal using the results of *ab initio* calculations on relatively large "pattern" molecules including 1,1,3-trimethyl cyclohex-2-ene and crotonaldehyde. The geometry employed is that given by Hamanaka *et al.*⁶ with the modification that all carbon-hydrogen bond distances are set equal to 1.08 Å and the side chain is idealised (that is, the carbon-carbon single and double bond distances are set equal to 1.50 Å and 1.34 Å respectively). This modification allows simulation of the side chain from a small number of pattern molecules. We have found that the results of the simulated *ab initio* molecular orbital (SAMO) method are of comparable accuracy to those that would be obtained by using the much more expensive complete *ab initio* approach. Although the full results of our SAMO calculation on retinal will be published elsewhere we report here some interesting features which may help in understanding the above enigma.

In Fig. 1 we show the numbering scheme used for all-trans retinal. We shall label the occupied π orbitals, in decreasing order of energy, as $\pi_1, \pi_2, \dots, \pi_6$ and the virtual (unoccupied) π orbitals, in increasing order of energy, as $\pi_1^*, \pi_2^*, \dots, \pi_6^*$.

The total overlap populations of all-trans retinal show the π bonding character to be weakest in the region of the C₁₁-C₁₂ bond. From this, in the ground state one would

Fig. 1

Table 1 Total Overlap Populations for Various Configurations of All-trans Retinal

Configuration	Bonds			Energy of transition (a.u.)
	C ₉ -C ₁₀	C ₁₁ -C ₁₂	C ₁₃ -C ₁₄	
Ground state	0.23488	0.23180	0.23545	
$\pi_1-\pi_1^*$	0.06285	0.07087	0.12687	0.35107
$\pi_2-\pi_1^*$	0.14382	0.10610	0.10672	0.40001

expect isomerisation to be favoured at this position. This feature, although it has been observed from the much less accurate Pariser-Par-Pople (π electron only) calculation of Pullman and Pullman⁷, has now been confirmed by our more accurate all electron method.

Although the SAMO method produces both occupied and virtual orbital energies for the ground state, since it does not explicitly use electron repulsion integrals, we have been unable to perform configuration interaction calculations. We have, however, been able to estimate the total overlap populations for various configurations. The lowest energy $\pi-\pi^*$ triplet state will best be described by a mixing (configuration interaction) of a number of configurations each formed by the promotion of an electron from an occupied π orbital to a virtual π^* orbital. The lowest-lying virtual π^* orbital, namely, π_1^* , is very much lower (having an energy of 0.02689 a.u.) than the other π^* orbitals. The most important of the configurations describing the $\pi-\pi^*$ excited state will be the $\pi_1-\pi_1^*$ configuration. The next most important will be the $\pi_2-\pi_1^*$. The total orbital populations for these configurations in the ground state are shown in Table 1. Configurations arising from the promotion of an electron from π_1 or π_2 to π_2^* are likely to make very small contributions to the $\pi-\pi^*$ excited state, because of, first, the energy difference and, second, the symmetry of the orbitals locally within the chain. The π orbital population in the $\pi_1-\pi_1^*$ configuration shows that bonds C₉-C₁₀ and C₁₁-C₁₂ are weaker than all other double bonds, the C₉-C₁₀ bond being marginally weaker than the C₁₁-C₁₂ bond. In the $\pi_2-\pi_1^*$ configuration, however, the C₁₁-C₁₂ bond is substantially weaker than the C₉-C₁₀ bond. Thus although we were unable to estimate the amount of mixing of these two configurations, it would seem feasible that there is a sufficient contribution from the $\pi_2-\pi_1^*$ configuration to make the C₁₁-C₁₂ bond the weakest double bond in the excited triplet state.

This leads us to suggest that the preferred isomerisation about the C₁₁-C₁₂ bond is due to the weak nature of this bond in the excited triplet state and that this would be established by a detailed all electron *ab initio* configuration interaction calculation. Such a calculation is economically impossible at present so that the conclusions from our simulated *ab initio* study are of some interest.

We thank Dr G. Pitt, University of Liverpool, for helpful discussions.

Formation and Breakdown of Aggregations of the Crown-of-Thorns Starfish, *Acanthaster planci* (L.)

IN spite of its notoriety, population densities of *Acanthaster planci* (L.) on most flourishing reefs in the Indo-West Pacific are low. It is possible, however, to find reefs in the region which support aggregations of hundreds or thousands of this starfish¹⁻⁸. In the Sudanese Red Sea we usually found *A. planci* densities of 5 to 20 per km of reef face, but on four reefs aggregations of several hundreds within a few hundred metres were studied⁹. These starfish were not evenly distributed but were usually separated into small subgroups of up to fifteen animals. Such subgroups tended to be associated with favoured species of corals, such as *Goniastrea*, *Turbinaria*, *Montipora* and tabular *Acropora* spp., whose shapes allowed several individuals to feed together and provided shelter from daylight.

We observed that *A. planci* leaving a completely eaten-out *Acropora* table often moved to other tables on which starfish were already feeding, rather than to tables which were as yet untouched. Such observations suggested some form of attraction between individuals. This appeared to influence the aggregation as a whole and our marking studies showed that its integrity was maintained over 3 months, implying some cohesive force. Nocturnal observations were made on the behaviour of two subgroups using tags to identify individuals. In Fig. 1 the mean distances between all the marked starfishes (the proximity index) are plotted against time. This index reveals that within the subgroups, starfishes moved closer together after nightfall once feeding had begun, and it suggests that feeding individuals exert a chemo-attractive influence on hungry starfishes nearby.

To extend our investigations into this possible chemo-attraction mechanism we sought to demonstrate that hungry starfish would select between two alternative food sources provided for them. Preliminary experiments using two large wire mesh Y cages arranged on the seabed were carried out. These allowed hungry starfish to move freely from the shelter of dead corals provided in the stem of the cages, and to choose

Fig. 1 Variation in the mean inter-starfish distance (proximity index $P^* = \sum |x^i - x^j| / [n(n-1)]$; $i \neq j, i, j = 1, 2, \dots, n$) with time for two groups (○ and ●) of *A. planci* studied at night. The index for both groups decreases after 2 h when some of the starfish had started feeding. The observation areas were 15 m² and there were eight starfish in each group.

Fig. 2 *Arothron hispidus* (L.) feeding on *Acanthaster planci*.

between potential sources of attractant, including other *A. planci* already feeding, located in the arms of the Y. These experiments, which were run at night, indicated an order of preference of attractants in which feeding *A. planci* were more effective than live coral alone, which in turn was more attractive than dead coral.

Because of the mesh structure of the cages, and the possible effects of currents of seawater, it was decided to abandon these tests in favour of a Y maze which took the form of a large aquarium. The base of the Y stem was relatively deep (0.5 m) and allowed seven or more experimental starfishes to hide under shelter during daylight. Seawater was pumped into the arms of the Y maze fresh from the sea. This caused equal currents to pass along each arm, over the attractant sources provided there, towards the base where it flowed out of the system. At dusk the experimental animals became active, and on moving could choose to enter either of the arms. The positions of the alternative attractant sources were reversed from night to night in each experimental series to rule out any inbuilt bias of the maze.

To date, this apparatus has yielded the following results. First, *Acropora* sp. against no attractant: thirty-nine choices to fifteen ($\chi^2=10.67$, $P<0.05$). Second, *A. planci* feeding on *Acropora* sp. against no attractant: thirty-one choices to eleven ($\chi^2=9.52$, $P<0.05$). Third, *A. planci* feeding on *Fungia* sp. against intact *Fungia*: thirty-four choices to fourteen ($\chi^2=8.33$, $P<0.05$).

The first result indicates that *A. planci* navigates towards its prey by chemosensory means like other asteroids (R. J. M., unpublished, and refs 10 and 11) and the second and third show that the feeding activity of *A. planci* on coral releases material which, in favourable conditions, will stimulate other starfish towards its source. This we regard as evidence for our chemo-attraction theory.

Our observations on the chemo-attraction effect in the feeding starfish have led us to propose the following model for aggregation formation. The distribution of low-density populations may be explained as a function of recruitment from dispersed settling larval starfish and the independent migration of solitary adults. An orthokinetic effect³ may serve to influence adult movements, as their rate of progress over the reefs is almost certainly affected by the ease with which they can find adequate food and shelter from daylight.

We found that starfishes preferred areas which were not too exposed to turbulence, not sandy and in which there was an adequate supply of preferred food corals. Within particularly favoured areas the effects of this mechanism, probably enhanced by chemotaxis towards preferred corals, may be sufficient to lead to slight local aggregations. At this state a critical effect seems to operate, for when the starfish come close enough for them to perceive the chemo-attractants described above, the

subgroups of the aggregation form. Local environmental changes may also occur which enhance the development of these subgroups, which we found to develop at densities of thirty to fifty individuals per km of reef face.

We also believe that the activities of an aggregation may influence larval survival and recruitment of juveniles to the population with important consequences in the long term. The increased proximity of adult starfishes may enhance the chances of fertilisation, especially if synchronous spawning takes place as has been described for other echinoderms¹²⁻¹⁴. Further, our group has recently demonstrated that the larvae of *A. planci* settle preferentially among clean calices of some species of coral and also that living corals prey on settling larvae (M. F. Barker, unpublished). Thus, as Cheshier suggested¹⁵, the destructive influence of aggregated adult starfishes will allow an increase in the successful recruitment rate of the juveniles, as in these circumstances larval settlement will not be accompanied by such high mortality. This consideration indicates that the population density of *A. planci* at which aggregation into groups begins may constitute a threshold beyond which a population explosion is likely to occur. The populations of *A. planci* may therefore be particularly sensitive to small changes of significant environmental factors which could result in densities in the region of this threshold; whether as a result of migration and convergence of adults, or due to an initial small increase in juvenile recruitment. Such small changes may be natural or man made.

Our research has indicated that the predatory behaviour of certain species of fish may be important in controlling the densities of adult *A. planci* in the central Red Sea. By continually working under water on one particular reef, many fish became accustomed to the presence of our divers so that their behaviour could be freely observed. Thus, two previously unreported predators of *A. planci* were discovered: the puffer fish *Arothron hispidus* (L.) (see Fig. 2) and the trigger fish *Balistoides viridescens* (Bloch). Both these fish attacked in a characteristic fashion, and the puffer fish left readily recognisable remains in the form of a circlet of detached starfish rays. The trigger fish *Pseudobalistes flavimarginatus* (Rupp), previously reported as a predator of the crown-of-thorns¹⁶, was also seen attacking it in the Red Sea. If these predators respond to an initial increase in the starfish population by feeding more frequently on *A. planci*, they may be capable of an early breakup of an aggregation. Thus if the formation of small aggregations of the type we have been studying is a critical stage in population explosion, these fish predators may be a particularly significant factor in controlling rapid increases in the sizes of *A. planci* populations.

We thank the Overseas Development Administration of the UK Government and the Royal Society who have supported our work. The photograph (Fig. 2) is by P. J. Vine.

A Photostable Pyrethroid

THE natural pyrethrins (see refs 1 and 2 for references) (for example, pyrethrin I (1)) and related synthetic insecticides³ (allethrin (2), bioallethrin (3), resmethrin (4), bioresmethrin (5), Cismethrin (6) and the ethanochrysanthemate (7)) are unstable in air and light (see refs 1 and 2 for references, and ref. 4). This property restricts their use, particularly against pests of agricultural crops, in spite of other favourable characteristics (see refs 1–3 for references) (outstanding potency against many insect species, rapid action, and low mammalian toxicity⁵). We describe here new synthetic esters, ten to one hundred times more stable in light than previous pyrethroids, yet as active against insects as bioresmethrin (5) and with low mammalian toxicity.

A recent modification⁶ of the acid component of bioresmethrin (5)^{7,8} gave a compound (8), 5-benzyl-3-furylmethyl (1R, trans)-2,2-dimethyl-3-(2,2-dichlorovinyl) cyclopropane carboxylate,

pyrethronyl ($R^2 = -CH=CH_2$)

allethronyl ($R^2 = -H$)

5-benzyl-3-furylmethyl

3-phenoxybenzyl

more potent than most known insecticides (LD50 0.1–0.3 mg kg⁻¹ to houseflies and mustard beetles). Chemical considerations⁹ and spectroscopic evidence indicated that the furan ring in esters of 5-benzyl-3-furylmethyl alcohol was a probable site for photosensitised attack by oxygen (now confirmed for resmethrin¹⁰). Therefore we examined esters of the modified acid with other alcohols. Other esters of potentially photostable alcohols (for example, 2,4-dimethyl benzyl¹⁰, 2,4,6-trimethylbenzyl¹¹, 6-chloropiperonyl¹⁰ and 3-benzylbenzyl¹² even with the most effective acids such as chrysanthemic and ethanochrysanthemate¹³ have been insufficiently active for practical application. In contrast, the ester (9) of 3-phenoxybenzyl alcohol¹⁴ with the 2,2-dichlorovinyl acid was more active against insects than would have been predicted. It was as potent, for example, as bioresmethrin (5) to houseflies and over 2.5 times more potent to mustard beetles; the corresponding (±)-cis,trans esters (11) and (4) had comparable differences in activity. The ester (11) was also three to four times as effective as the corresponding chrysanthemic to *Anopheles stephensi* females and *Glossina austeni* (mixed sexes) (results communicated by F. Barlow).

To determine the stability in light of the new esters, deposits (0.2 mg cm⁻²) were exposed to daylight near a window indoors. In these conditions 50% (determined by gas chromatography)

§§ Administered in arachis oil.

of esters (4-7) of 5-benzyl-3-furylmethyl alcohol was lost in 4-6 h whereas the 3-phenoxybenzyl ester (11) lasted longer than 3 weeks. Similar deposits were also exposed out of doors under quartz plates which shielded them from rain and wind but admitted ultraviolet and visible light. In these accelerated tests, where films attained up to 50°C in bright weather, bioresmethrin (5) lasted 1-2 h, compared with about 4 d for the 3-phenoxybenzyl ester (11). Bioassays of deposits with *Drosophila melanogaster* also indicated comparable persistence of insecticidal activity, showing that the photodecomposition products were not toxic to insects in these conditions.

Although such greater stability should extend scope for pest control, persistence of the new esters is moderate and therefore the advantage of freedom from toxic residues should be retained. In addition, their mammalian toxicity is low (see Table 1); for instance, the ($\pm$)-*cis,trans*-dichlorovinyl ester (11) containing about 20% of *cis* component (easily obtained by heating the mixed acid chlorides before esterification), like resmethrin (4), had lower oral and intravenous toxicities to rats than pyrethrin I (1) or bioallethrin (3).

Work is in progress to identify the photodecomposition products and mammalian metabolites of the dichlorovinyl esters and to establish the behaviour of the compounds under practical pest control conditions.

The new compounds are protected by UK Patent Applications Nos 30838/72 and 59184/72. We thank Dr J. M. Barnes and Mr R. D. Verschoyle for communicating mammalian toxicity data, Mr F. Barlow for results with *Glossina austeni* and *Anopheles stephensi*, and the National Research Development Corporation for financial support.

and so refs 10 and 11 on Fig. 2 should be changed to 14 and 15 respectively.

Erratum

IN the article "Transcellular Strands of Cytoplasm in Sieve Tubes of Squash" by Robert Thaine and Margaret E. De Maria (*Nature*, **245**, 161; 1973) Fig. 2 was reproduced on too small a scale for the salient features to be clearly visible. It is reproduced again here.

Fig. 2 *a*, An electron micrograph from a transverse section of a sieve plate in which pores have a tubular lining of densely stained material. The bar represents 2 μ m. *b*, An electron micrograph from a longitudinal section showing a strand extending from a sieve pore (SP) into the sieve element. W, Sieve tube wall. Black arrow, plasmalemma; white arrow, a group of parallel structures which can be followed from the constricted end of the broken strand (see text). The bar represents 2 μ m.

P.O. BOX 211
AMSTERDAM
THE NETHERLANDS

Full data on all patents from 24 countries in minutes!

Derwent Publications introduces the world's fastest and most comprehensive information service on patents.

Now that patent specifications filed in Japan and many European countries are published so rapidly, they are replacing conventional trade and scientific journals as sources of information on new ideas and latest developments. Also, they provide advance information on related patent applications which will be published much later by the United States and United Kingdom patent offices.

This new interest in patents has intensified the need for a simple international patents journal wherein the whole of the patent literature of the World can be scanned, and items of interest followed up, in a unified system.

From January 1974 Derwent will be providing a new integrated service – World Patents Index – which will completely meet this need.

Each week computer-generated and phototypeset WPI covering *all* subjects will give fully indexed information on over 12,000 patents published 4–5 weeks earlier in 24 major countries. In a single gazette WPI will contain indexes which will allow in a matter of minutes searching by patentee, subject matter and keywords and will identify families of patents.

Back-up information for WPI in the form of English language abstracts for chemical subjects is provided by the highly successful Central Patents Index, operative since 1970. A companion

service for non-chemical subjects – General Patents Index – will commence at the same time as WPI. Each week GPI will publish, in book and card forms, abstracts plus drawings, available for convenience in three separate sections – General, Mechanical and Electrical.

Additional services to subscribers include:
High speed central bureau patent searches
Selective monitoring by subject, country or patentee
Copies of patent specifications on request.

No other source is able to provide patents information of such depth, accuracy and speed. Furthermore, the many advantages of these outstanding services can be obtained for a really economical subscription equivalent to only a few pounds a week.

Towards the end of November, samples of WPI and GPI will be available for you to evaluate without obligation and completely free of charge.

Write now (quoting DM) for brochure, giving full details of these services and subscription rates, and for the free samples.

World leaders in patents information.

BOOK REVIEWS

The Art of Science

From Stonehenge to Modern Cosmology. By Fred Hoyle. Pp. 96. (W. H. Freeman: San Francisco and Reading, March 1973.) £2.10.

AN art historian from Vienna once gave me his personal view of contemporary art—and here I extrapolate freely from memory—that the art of the times is science. He held that some day we will look back on our present science as an essentially religious enthusiasm and the cyclotrons and telescopes that did this science as representative works of folk art.

It is fascinating to read, then, Fred Hoyle's absorbing analysis of Stonehenge as an ancient astronomical observatory. It feels right that the stone age builders of this monument, inextricably close to their environment, should be strongly aware of the eclipses of the Sun and the Moon. It is an intellectual pleasure to follow Hoyle's reconstruction of how the post holes and sighting lines enabled eclipses to be predicted. It was an elevating thought for me to consider that these ancients, with their stone age orrery, had probably a simple, accurate grasp of the spatial relationships of their nearby, celestial neighbours.

But then the question arises: Why did the functions of Stonehenge I decay? Did the early Britons find the smelting of metals more useful than the predicting of eclipses? It now becomes clear that of the four short lectures that comprise this ninety-three-page book, the one on Stonehenge should have come first. The one that is actually first, "Science and Society in Modern Times", should have come second because it raises the question of what makes a society rise and decline. Hoyle notes a tension between science and society. He notes the obvious fact that science, technology and its long range consequences are not deeply understood by many politicians. Hence science is often applied destructively rather than constructively to society. But he does not discuss what is, to me, the more crucial point; that is, the effect of society on scientists. Surely scientists reflect the competitiveness and insecurity of their milieu. They manoeuvre for pre-eminence, squabble over marginal doctrinal issues, and only unite to suppress the threat of new ideas. The real tragedy—beyond the fact that science is not much fun under these conditions—is that science is then misapplied by shortsighted or unscrupulous people from other sectors of society. The scientists have no effective

chance of ensuring that their product is used constructively because they are totally disunited.

If we were ever to live in a healthy, friendly, intelligent world, perhaps the last two chapters in this book would furnish us a glimpse of the kind of activities we would be engaged in. The broadest possible questions are addressed—like the distances of quasars and galaxies, the nature of mass, the phenomenon of seafloor spreading in the Earth. Hoyle faces the hard observational evidence for discrepancies in the conventional cosmology and tries to gain understanding by connecting inferences from many fields of astronomy, physics, and science. Needless to say, his suggestions are considered controversial. It is often said about someone who is obviously very bright, but clearly a non-conformist that, well, maybe he is incorrect but he is valuable because he stimulates thought. That is not quite the point. On many of the issues raised in this book there are right and wrong answers. At least there are some answers that are a good deal more correct than others. About only one thing can we be fairly certain and that is that the *status quo* is incomplete. If we have much of a future, our current understanding of reality will eventually appear extremely primitive. Which are now the most correct answers?

If we progress in our understanding it will have to be through an unprejudiced awareness of our environment. Perhaps the builders of Stonehenge I had such a harmonious attitude toward their surroundings. Perhaps some day we will pursue fundamental questions such as what is the nature of the universe in a more leisurely and co-operative fashion, like an art. And perhaps that will be the most rigorous analysis of all.

HALTON ARP

Buffalo

The Time of the Buffalo. By Tom McHugh with the assistance of Victoria Hobson. Pp. xxiv+339+xi. (Alfred Knopf: New York, December 1972.) \$10.

THIS is a long, in parts detailed but for the most part readable book about both North American subspecies of the so-called buffalo—*Bison bison bison*, the plains buffalo, and *B. bison athabasca*, the wood buffalo. To a much lesser extent it is also about their ancestors and near relatives. It is not clear, however, what readership the author had in mind when writing it, although the somewhat vague, rather nostalgic title

seems to suggest that a wide market is envisaged. This lack of focus may be a consequence of the author's three professional interests: research zoologist with a special interest in animal ecology and wildlife management; author; and photographer for several of Walt Disney's True Life Adventure films, including *The Vanishing Prairie*. It is most certainly not a book for the anatomist, physiologist or palaeontologist and scholars interested in the historical aspects of the buffalo will find that it lacks the depth of Frank G. Roe's *The North American Buffalo: a Critical Study of the Species in the Wild State* (University of Toronto Press, Toronto, 1970).

Much of the book is concerned with the Indians' use of and attitude towards the buffalo at and immediately after the period of first white contacts but it is not a significant contribution to cultural anthropology. The author's real contribution is that, working as an animal ecologist, he has spent considerable time observing at close range the present-day herds in Yellowstone National Park, Wind Cave National Park, the Wichita Wildlife Refuge, the National Bison Range and the Crow Reservation. His objective in doing so was to try to answer some of the "legacy of questions" left by the "vast literature on the beast", not by a further re-sifting of the literature but by personal observations. How did hide-hunters manage to kill large numbers from a single group without frightening the survivors? Did the vast herds wander erratically or make precise annual migrations? Did vast numbers actually die in blizzards, drownings, quicksands and prairie fires? It is from his own observations that the author contributes most in attempting to answer questions like these and it is when he writes of these observations that he is at his most compelling.

Not surprisingly, in the light of the author's professional experience as a photographer, the book is illustrated with some excellent monochrome prints of buffalo in action: at birth and play; wallowing and fighting; and being lured into traps by the author's successful application of the techniques employed by Indian decoys. One would have welcomed more of these, even if it had been at the expense of some of the reproductions of nineteenth century etchings, paintings and photographs of buffalo hunts and hunting techniques. Four pages of maps are given pride of place at the front of the book. These are useful but the two showing the whole of North America lack clarity. There

is a nineteen-page bibliography and the book is generally well produced.

G. MALCOLM LEWIS

Industry and Education

The Universities and British Industry, 1850-1970. By Michael Sanderson. Pp. x+436. (Routledge and Kegan Paul: London, December 1972.) £6.50.

OVER the greater part of the nineteenth century the ancient universities of England were indifferent to industry and did nothing to encourage graduates to take up industrial careers. On the other hand, the provincial universities, founded after 1850, began as science colleges and were always sensitive to the needs of local industry; this was also true of most of the London colleges. By 1914 the universities, including the appropriately reformed Oxford and Cambridge, were able to make considerable technological contributions to the war effort, and they were able to repeat this service during the Second World War. Since 1945 there has been a proliferation of new universities and a great increase in the number of subjects available for study.

Dr Sanderson has chronicled these developments, which I take to be fairly well known, in some detail and he has confirmed most of the conclusions we usually draw from them. He discusses the English university institutions in relation to industry and he has chapters dealing with the Welsh colleges and (particularly interesting) the Scottish universities as well as with special topics such as commercial education and the woman graduate in industry and commerce. He has studied the main sources of support of the universities and has examined the distribution among faculties and subsequent careers of the students. He has sifted an immense amount of material. But there are so many universities and so great is the scope of industry that his work has certain obvious limitations. Apart from Belfast and Coleraine, the Irish universities are not mentioned although they were in the United Kingdom for more than half Dr Sanderson's period. American, French and German institutions come only very marginally into the story, while technical colleges are mentioned only when they become universities. Unsuccessful attempts to found universities are ignored: there is no mention of, for example, the interesting proposal, a hundred years ago, to found a Western University in the Vale of Neath.

Universities, however, do not exist in a social void. The development of British universities, and hence their value to industry, was necessarily restricted by the unsatisfactory state of

primary and secondary education before 1902, the inadequate scholarship ladder and the expense of attending a British compared with a German university. Dr Sanderson does not mention these aspects of the story and he does not comment on the long debate about the role of examinations in university education, to which was related the nineteenth century failure to develop research training. These factors account, in part, for the domination of British industry, and even of British scientific education, by Germans in the early 1900s; a domination that Dr Sanderson notes but does not analyse. Parenthetically, it is notable that the phenomenon was most conspicuous in manufacturing areas of "high technology", such as the Manchester region. The contemporary response included the heroic efforts of Sir Norman Lockyer and the establishment of the British Science Guild.

I am, therefore, puzzled by Dr Sanderson's conclusion that the best British universities had, by 1914, caught up with their German equivalents. Many novel features of British universities in the early years of this century had been explicitly copied from German practice: Imperial College was called the "London Charlottenburg". By 1914 the great majority of professors of chemistry in British universities had German PhD degrees. And, if the situation was by then so satisfactory why was it later thought desirable to introduce the German PhD system into this country?

In fact the tenor of Dr Sanderson's argument is that, generally speaking, we may congratulate ourselves on the way things have gone. Indeed he is almost complacent in his comment that we have avoided the "dualism" of universities on the German model, divided as they are between the traditional and the technological. Surely we are not called on to commiserate with, for example, the Swiss since Zürich is lumbered with both a traditional university and the Federal Institute of Technology?

In short it is not easy to grasp the point of this book. It brings to light no serious problems, hitherto unnoticed, and because of the enormous range of the subject matter it cannot deal in depth with specific issues. I assume therefore that Dr Sanderson intends it as a pilot study and will now go on to make detailed investigations of individual topics. Certainly one hopes that this is the intention; there are, after all, enough problems of modern and of historical importance to deserve the attention of a scholar like Dr Sanderson who is not afraid of hard work and who is capable of dealing with great quantities of intractable material.

The minor criticisms of this book must reflect the interests of the individual reviewer. It is clear to me that Dr Sanderson overlooks the sharp distinction that Whewell drew between "established" sciences (astronomy, mechanics) and "progressive" sciences (such as botany, zoology); it was the latter, Whewell argued, that should not be taught to undergraduates. He is also rather less than fair to Mark Pattison, who became a progressive in his later years and played a part in the "endowment of research" movement. As an adoptive Mancunian I object to Dr Sanderson's cavalier spelling of Fairbairn's name. I think he exaggerates, at the expense of Harwood and Bateman, the part played by Roscoe in the Thirlmere scheme. And, much more serious, he does not mention George Davis, the pioneer of chemical engineering as an academic subject (see his *Handbook of Chemical Engineering*, 1901). Finally, it should be pointed out that only a part of the Royal Navy Signals School, later the Admiralty Signals and Radar Establishment, was moved to Bristol University during the last war; other portions went to places like Haslemere and Witley.

WILEY INTERSCIENCE

HOMOGENEOUS HYDROGENATION

Edited by **Brian R. James**, *University of British Columbia*.

Deals exhaustively with this vast topic and reviews literature from the first reported studies in the mid-thirties to the end of 1970 (an appendix surveys literature from 1971 to mid-1972). Classification of material is based on metal triads with cross references where necessary.

September 1973 543 pages £12.50

NMR SPECTRA OF SIMPLE HETEROCYCLES

By **T. J. Batterham**, *Australian National University, Canberra*.

A critical survey of all papers (from 1960 to 1970) dealing with any aspect of the NMR of the simple heterocyclic systems. Provides enough tabulated data so that it can be used as a handbook for identification of these ring systems, and refers to literature on many more complex ring systems. (General Heterocyclic Chemistry Series, Volume 2.)

September 1973 560 pages £18.75

MOLECULES IN THE GALACTIC ENVIRONMENT

Edited by **M. A. Gordon**, *National Radio Astronomy Observatory, Virginia, U.S.A.* and **L. E. Snyder**, *University of Virginia, Virginia, U.S.A.*

The book results from a symposium attended by chemists, physicists, biologists and astronomers attempting to ascertain what new research is required to understand the presence of complex molecules in space. The resultant astronomical observations which emerged can be observed as the foundation of a new chemistry.

October 1973 494 pages £9.50

MARINE EVAPORITES: Origin, Diagenesis and Geochemistry

Edited by **Douglas W. Kirkland** and **Robert Evans**, both of *Mobil Research and Development Corp.*

The first modern treatment of the origin of the common evaporites. Considers in detail the deposition of the carbonates, gypsum, anhydrite and halite from different environments including sabkhas, deep and shallow lagoons, and broad shelf and elongate estuaries. May be used as text for a course of the origin, chemistry and alteration of the non-potash precipitates from sea-water. Includes editors' commentaries and author and subject indexes. (Benchmark Papers in Geology.)

November 1973 442 pages £10.00
Published by Dowden, Hutchinson and Ross, Inc., and distributed by John Wiley and Sons, Ltd.

ADVANCES IN SATELLITE METEOROLOGY No. 1

By **A. I. Burtseva** and **P. N. Belova**, Both of the *Soviet Hydrometeorological Centre, Leningrad*.

These two volumes collect papers that were originally published by the Soviet Hydrometeorological Centre as part of the Proceedings Series (Trudy Nos. 72 and 89). The papers deal with interpretation of photographs obtained from weather satellites and their application to weather analysis and forecasting. (Translated from the Russian 1973, first published in Leningrad 1971.)

September 1973 312 pages £7.50
Published by Israel Program for Scientific Translations Ltd., and distributed by John Wiley and Sons, Ltd.

EGO FUNCTIONS IN SCHIZOPHRENICS, NEUROTICS AND NORMALS: A Systematic Study of Conceptual, Diagnostic and Therapeutic Aspects

By **Leopold Bellak**, *New York University* and **Albert Einstein College of Medicine**, **Marvine Hurvich**, *Roosevelt Hospital, New York*, and **Helen K. Gediman**, *Albert Einstein College of Medicine*.

The result of a five-year research study of the schizophrenic syndrome as a variable disorder of ego functions. Reviews literature on ego functions, then describes experimental study, giving data and process and applies them to diagnosis, treatment and prognosis. (Wiley Series on Personality Processes.)

October 1973 586 pages £10.00

CHEMICAL STERILIZATION

Edited by **Paul M. Borick**, *Ethicon Inc.*

Papers selected by the editor from the worldwide primary literature. Deals with various antimicrobial agents and explores their practical as well as theoretical aspects. Editor's commentaries, author and subject indexes are included. (Benchmark Paper in Microbiology)

November 1973 366 pages £9.00

Published by Dowden, Hutchinson and Ross, Inc., and distributed by John Wiley and Sons, Ltd.

NEUROCHEMISTRY OF CEREBRAL ELECTROSHOCK

By **Walter B. Essman**, *Queens College of the City University of New York*.

This volume presents both an extensive review as well as a summary of original experimental findings of the changes in brain chemistry associated with cerebral electroshock. As a method for the investigation of seizure mechanisms, as a therapeutic medium and as a memory destructive stimulus, cerebral electroshock has provided a basis for neurochemical investigation in both brain tissue and cerebral spinal fluid. The present volume has been organised around the concept of molecular changes as these concern specific metabolic systems in the brain and those changes brought about therein by cerebral electroshock, seizures, or convulsions.

October 1973 190 pages £6.25
Published by Spectrum Publications and distributed by John Wiley and Sons, Ltd.

METHODS IN IMMUNODIAGNOSIS

Edited by **Noel R. Rose** and **Pierluigi E. Bigazzi**, *Center for Immunology, State University of New York at Buffalo*.

Immunodiagnosis denotes the many applications of immunological methods to the diagnosis of human disease. Because of the rising importance of these methods, a laboratory course was given by the Center for Immunology in 1969 and 1971; this volume is derived from the laboratory guide of that course and has been updated to include more recently adopted methods. Emphasises procedures that are not extensively described in existing books of immunochemical or biochemical methods, and presents underlying principles that are broadly applicable to immunodiagnosis. (Techniques in Pure and Applied Microbiology.)

September 1973 224 pages £6.50

Forces and Particles

An Outline of the Principles of Classical Physics

A. B. Pippard

By developing the central ideas of classical physics from an experimental rather than a mathematical point of view, this book stresses the common soil from which so many varied applications have sprung, and helps the student to see how ideas from one field can illuminate another. The treatment is taken to the point where the limitations of classical concepts become apparent, and brief accounts are given of the way in which quantum mechanics and relativity set out to enlarge the compass of physics. At every stage there are references to more specialised treatment.

Wealden Geology

Geology of the Country around Royal Tunbridge Wells. (Memoirs of the Geological Survey of Great Britain, England and Wales.) By C. R. Bristow and R. A. Bazley. With contributions by R. W. Gallois, E. R. Shephard-Thorn, R. Allender, R. Casey and H. C. Ivimey-Cook. Pp. x+161 (9 plates). (HMSO: London, November 1972.) £2.

THE memoir is an explanation of One-inch Geological Sheet 303, New Series, which was resurveyed in 1960–1965 and published in 1971. The area is centrally situated in the Wealden Basin, and at outcrop the solid rocks are almost all of Wealden age with a very small area of Purbeck strata in the extreme south-east. The memoir includes an account of the stratigraphical palaeontology of Jurassic strata penetrated by the Ashdown boreholes, one of which terminated in undated, pre-Jurassic sediments.

After an introductory section, the remaining seven chapters deal with structure, concealed formations, the Jurassic, the Cretaceous, the Pleistocene and Recent deposits, superficial structures and economic geology. Each chapter is composed of individual (initialled) paragraphs by the field surveyors and specialist contributors, which generally fit together well to give a thorough account of the area. An anomaly arises because of the unfortunate use of "Jurassic" and "Cretaceous" as chapter headings: the Purbeck Beds are discussed under the Jurassic despite the apparent acceptance of Casey's views on the age of these beds.

Of the eight chapters, that on the Cretaceous (Wealden Beds) occupies seventy-one out of the 123 relevant pages. There is a general account of the Hastings Beds Group, which is divided into five mappable formations (the term "formation" in parentheses). These represent the deposits of three major cyclothems of deltaic sedimentation. Ostracods provide the most useful zonal fossils, and F. W. Anderson has recognised three *Cypridea* zones. Field mapping indicates that certain stratigraphical names, including "Fairlight Clays", should be abandoned.

Detailed description of Wealden sections occupies fifty-four pages. This contrasts with the brevity of the chapters on superficial structures and on economic geology, which together occupy seventeen pages. For the section on superficial structures a sketch map to illustrate areas prone to surface movement (landslipping, cambering and valley bulging) would have been useful. The chapter on economic geology consists of brief accounts of past and present working for material such as Wealden iron, brick-clay, cement and lime, building stones and oil and gas.

As such it is an interesting historical survey but of limited present day significance. Sand and gravel, for example, are discussed in three short paragraphs, despite the extensive areas of outcrop of sandy formations. Although "no large commercial organisations are utilising this source of sand at present, probably because the sand is too fine for most purposes", an assessment of possible industrial uses, or even of reserves, would be invaluable.

In summary, the authors have produced a good and attractive memoir within the limitations imposed by the standard framework of the sheet memoir series. One is left wondering for whom the Institute of Geological Sciences produces these publications, which have evolved so little in style and content. With the increased emphasis on mineral assessment and other aspects of economic geology within the institute, it could be useful to expand the economic side of the memoirs, possibly at the expense of detailing innumerable local sections.

P. F. RAWSON

Adventurous Physics

Forces and Particles: An Outline of the Principles of Classical Physics. By A. B. Pippard. Pp. xii+321. (Macmillan: Basingstoke and London, November 1972.) £5.75.

PROFESSOR PIPPARD explains in the preface that this book is an expanded version of his lectures to the "fast" stream of first year physics students in Cambridge. He refers to them as "those who wanted the more searching treatment", but certainly in my time the two courses which ran in parallel were referred to as "fast" and "slow". These are relative terms; to quote again from the author's preface, "Recognizing the impossibility of pleasing everyone, I have now addressed myself, as I did when giving the course, to the more adventurous who are prepared to work out for themselves congenial patterns of thought that will make sense of what can so easily remain a disorderly assembly of observations and ideas". This is not, therefore, a book for the average student, and it will not make a fortune for its publisher or its author. It is, however, distinctly possible that it will be an influential book, and it should be read by every physics lecturer, for we are in some danger of forgetting that these topics can be treated with this degree of elegance, economy and clarity.

The coverage is not as wide as the subtitle might suggest; it is restricted to dynamics and electricity and magnetism with brief incursions into relativity and introductory quantum mechanics. A few selected experiments are described in some detail. The order in which,

topics are treated is on the whole not unconventional. I found only one point at which I felt the book departed from the high standard of exposition and logical treatment which characterizes it; this is on page 194 where *D* makes a sudden appearance in circumstances where it might be confused with a depolarizing coefficient *D*, to disappear incidentally after the following page and find no mention in the chapter entitled "Maxwell's displacement hypothesis". There are some characteristically Pippardian asides on topics such as numerology. God, like *D*, is briefly admitted to a possible role (page 130) but is not in the index.

Altogether this is an excellent book in the best traditions of the Cavendish.

W. COCHRAN

A Modern Icarus

Flight and Nature. By M. W. Saunders. Second edition. Pp. vi+126. (M. W. Saunders: Chaldon, Surrey, 1972.) £4.80.

IN a book largely concerned with a theoretical synthesis of man-powered ornithopters, it is strange to find an introduction reiterating all the usual statements on man's ecological responsibilities, however valid such statements may be. The author seems to feel that the study of natural flight is a duty, though he has apparently made no investigations himself. As he puts it: "The main reason for studying ornithoptics and aero-ecology concerns the long term maintenance of our heritage. A broad and continuous investigation would seem appropriate". He also suggests that there is a "likelihood of beneficial offshoots concerning such matters as birdstrikes, aerodynamics, air traffic, etc.". It seems that the author believes that little is known about the flight of birds. His list of references makes no mention of some of the most valuable recent contributions.

The theoretical study is straightforward, though perhaps oversimplified in parts; but where he considers aspects of practical design the proposals are very questionable. There seems to be no realisation of the stresses on the structure, hinge joints, and so on, due to inertial loads. Frictional losses within the mechanism are dismissed; power transfer is supposed to be carried out by wires which the author says must be designed "to have a very low sliding friction. For example, they may slide in guide tubes and be supported: by a fluid medium, by rollers, or by coaxial springs". His proposals for instrumentation are even more obscure: "Information on the craft's performance could be conveyed to the aviator by means of earphones, such information could be verbal, or in the form of sounds related directly with performance.

Direct acoustic connection to the wing surface could be used if preferred".

There is reason for believing that any attempt to achieve man-powered flight by flapping wings must fail. The mechanical limitations imposed by the physiology of the living animal, such as blood circulation and growth, permit locomotion only by the use of oscillatory systems with their inherent problems of inertial forces. Such forces may well set a limit to the size of birds. Man-made devices using rotary motion are not limited by such alternating stresses.

It is true that, as the author says, there is much yet to be learnt about natural flight, but it will not be learnt by this approach.

R. H. J. BROWN

Thinking Computers

Problems of Heuristics. Edited by V. N. Pushkin. Translated from Russian. Pp. vi+202. (Israel Program for Scientific Information: Jerusalem; John Wiley: Chichester, March 1973.) £8.45.

THIS book is a translation—a very competent one—of a collection of papers published by the Institute of Psychology of the Academy of Pedagogical Sciences of the USSR in 1969. It gives one a fascinating glimpse into the current thinking of Russian psychologists about human thought and the problems of describing it in programmatic terms. Apparently there is as much lively discussion in the USSR as in the West of the possibilities and limitations of computer models of psychological processes; whatever the future of artificial intelligence and heuristic programming, it is good to see the issues discussed in such a thoroughgoing fashion.

The authors represent a wide variety of disciplines, including psychology, logic, pure mathematics and engineering. Their interests are reflected in the structure of the book, which is divided into four parts. Parts 1 and 2, entitled "Theoretical Problems and Heuristics" and "Experimental Studies and Heuristic Processes" respectively, are intellectually dominated by the editor's own contributions. He sees clearly the need to study human performance in order to construct effective algorithms for automatic process control and problem solving, and draws attention to the serious deficiencies of "stimulus-response" automata as models of human problem solving. What we need, he suggests, is a theory of "heuristic automata" which could model the elements of a given problem, construct systems from these elements and use the systems for solving the problem. Unfortunately there is no general theory of such automata at the present time.

The other two parts of the book are entitled "Programming and Components of Human Thought" and "Investigation of Reflexive Processes". The latter is the

shortest section and the most idiosyncratic; it deals with "devices which optimise their performance in response to human counteraction", and it is not clear that they have very much to tell us about human thought. But the main body of the book, represented by parts 2 and 3, is a mine of case studies of human beings attempting to solve simple (and not so simple) intellectual problems. There is a thoroughly professional chapter on the perception and recollection of board positions in chess, this study being backed up by observing the eye movements which accompany the examination of a board position in the process of attempting to memorise it or to solve a chess problem. There is a comparison between the performance of humans and computers in solving various kinds of rearrangement puzzles and a very long chapter on the famous problem of the fly which travels to and fro between two cyclists riding towards each other—though perhaps it generates more amusement than psychological insight. In part 3 the most interesting paper is one on the automatic design of pipelines, an exercise in cooperation between human designers and computing machines. It seems to be inspired by a good sense of the proper place for computers in human society.

H. C. LONGUET-HIGGINS

Medical Thoughts

Medicine and Society. By H. Miller. Pp. 87. (Oxford University: London, August 1973.) £2.25 library edition; 80p paper.

THIS is an excellent book that ought to be read by anyone with the slightest interest in medicine and medical services. In eighty pages Dr Miller gallops through (*inter alia*) drug development, operation of the National Health Service, staffing of hospitals, general practice, population screening, education, dentistry, genetics, abortion, euthanasia, transplants, contraception and the medical needs of the third world. He says something interesting and provocative about them all, and doesn't waste a word.

The Medical Research Council and molecular biology are rapidly dispatched in "it is still difficult to escape the impression that the collection of Nobel prizes and the headlong pursuit of the almost metaphysical harvest of molecular biology has taken precedence over the exploitation of science in the service of medicine and man". He clearly dislikes any thought that euthanasia might be available through the medical profession: "It might be more appropriate for an enthusiastic prelate to conduct the patient to the Elysian fields".

This is just the book for a ninety-minute train journey.

DAVID DAVIES

Rationalizing Water

Scientific Allocation of Water Resources: Water Resources Development and Utilization—A Rational Approach. By Nathan Buras. Pp. 208. (American Elsevier: New York; Elsevier: Amsterdam, 1972.) Dfl.46; \$14.50.

THE last decade has seen both a much greater awareness of the many severe and growing complications (technical, legal and social) in water resources studies and the development of powerful systems engineering techniques. The techniques, however, cannot yet cope fully with all the complexities of the overall water resources problem. Either the problem has to be simplified in certain aspects or the techniques are applied to particular components of the overall problem.

In the latter category, Buras has made notable contributions to the development and application of systems techniques in water resources engineering. His book shows succinctly (in 200 pages) his authoritative grasp of the subject and is to be welcomed for bringing together material dispersed over a plethora of journals and proceedings.

The preface and introduction give respectively lucid surveys of the book itself and of the historical background of water resource development from Biblical times onwards. The overlap of water resources engineering with many related disciplines in the pure and applied sciences and in the social sciences is well summarized in the introduction.

Chapter 2 sets out the philosophy of the systems approach to water resources studies, without obscuring that philosophy with mathematics. Summaries of applications of the approach in California, the Indus Valley and Israel are presented. Wisely, Buras stresses that the application of systems engineering to water resources problems is only in its initial exploratory stage.

After distinguishing between development problems, design problems and operational problems in chapter 3, he gives a full account of those probabilistic methods applied in water resources studies, with the minimum of mathematical obscuration, in chapter 4.

The optimization techniques widely used in water resources problems, and to which Buras has himself made many contributions, are set out in chapters 5, 6 and 7. Linear programming, with specific examples to lighten the basic material, is adequately covered in chapter 5. The main value of the whole book, however, may well be the thorough treatment given to dynamic programming methods, both as a way of approach and in their application, in chapters 6 and 7. These chapters seem to me to be the outstanding feature of the book, and will provide a sound insight to this complex subject. A brief

review of simulation methods is given in chapter 8.

This book fills a gap in the texts on water resources engineering. It deserves to be studied by all graduate students in the water resources field, and should be read by many others in the associated disciplines.

T. O'DONNELL

How Herbicides Work

Mode of Action of Herbicides. By Floyd M. Ashton and Alden S. Crafts. Pp. 504. (Wiley Interscience: New York and London, February 1973.) £12.50.

THIS book is a mine of information. It opens with a few general chapters on the economics of weed control and on the classification of herbicides and then proceeds to give brief comparative consideration of factors affecting uptake and translocation of herbicides, on their molecular fate in the plant and on the main kinds of biochemical responses of plants to their presence. This is followed by fifteen chapters, together occupying the greater part of the book, each dealing with a chemically defined group of related herbicides.

Each of these specialized chapters is arranged on a common plan. First, the herbicides themselves are defined and described. Next, their general macroscopic effects on plants are outlined and our knowledge of their uptake and translocation is summarized. Then follow sections on metabolic change of the herbicides in the plant, if any, and on the known biochemical responses of the plant in the period preceding death. This latter is usually the largest section in each chapter. A final section summarises present views on which of the induced biochemical abnormalities are most clearly associated with plant death. Each chapter is provided with a well chosen set of references so that any point of special interest to the reader can be easily followed up.

The modern herbicides are virtually all products of the last thirty years or so; it is really notable how much work has been done on their physiological and biochemical effects. Two main observations can be made on the results of this work. First, it is clear that very few herbicides indeed have a simply definable mode of action, at least in our present state of knowledge. Perhaps the best example of a simple mode of action is that of the nitrophenols; these compounds have been well known to biochemists for a long time as uncoupling agents and it seems that it is indeed this activity which is mainly responsible for their toxicity to plants. At the other extreme, the phenoxy-acetic acid hormone-type weed killers induce an enormous number of unrelated biochemical responses and we are still, after thirty years research, far

from being able to account for their important herbicidal activity.

The second general observation is that it is striking that few, if any, herbicides show a true specificity of action. Selectivity, when it occurs, is often based on crude mechanisms based on differential wettability of leaf surfaces, ease of uptake and translocation or access to root systems. Sometimes a more sophisticated mechanism is involved where selectivity is based on differential capacity to degrade the herbicide to less toxic derivatives. Specificity based on action at a specific site is not known, contrasting in this respect with some of the more selective antibacterial antibiotics.

This is a book which will interest not only the specialist working on herbicides but also many with a more general interest in the action of toxicants on living cells. It is a book that many would like to have as a reference book on their own shelves, but the price is scarcely encouraging.

P. W. BRIAN

Coastal Problems

The Water's Edge: Critical Problems of the Coastal Zone. Edited by B. H. Ketchum. (Coastal Zone Workshop held 22 May–3 June, 1972, Woods Hole, Massachusetts.) (MIT: Cambridge, Massachusetts and London, 1972.) £1.80; \$3.95.

A RECENT review of scientific, economic, social and political problems of coastal zones has been published from MIT—a result of a “workshop” jointly sponsored in 1972 by the US Institute of Ecology and the Woods Hole Oceanographic Institution and supported by NSF (RANN Program) and the Rockefeller Foundation.

As Hollings¹ has observed of another, similar exercise “the real success of the workshop rests as much with its style of operation as with its substance” but of its method of operation the book gives little clue. Chapters have been prepared by small, presumably editorial, groups, with “contributions from . . .”. This technique provides a pleasant uniformity of style, but one wonders how much dissension, argument and genuine difference of view has been incorporated.

The report considers, in turn, diverse aspects of coastal zone problems—those arising from cropping biological resources; from non-renewable resources of oil, gas, minerals, gravel; those posed by growing demands for recreation and amenity; those changes brought by urbanization, industrial development, navigation and waste disposal schemes.

It effectively distinguishes between exclusive uses of the resource (such as aquaculture, or nature reserves), multiple uses (such as water for industry, waste disposal) and displaceable uses (that is, those such as power stations which could

be located elsewhere), and sagely observes that the present sad state of many coastal sites is a result of their non-management as much as mismanagement.

From the British standpoint both comparable and contrasting views are indicated. First, the coastal zone is “a band of dry land and adjacent ocean space”—in effect extending over coastal plains, or even whole watersheds, to the edge of the continental shelf and beyond. The United Kingdom concept of coastal areas, by contrast, appears parochial, if more closely focused. Perhaps inevitably, the same conflicts of use emerge in both the USA and UK, and there is the same divisive confusion of land use planning, management and legislative authorities. It becomes a truism that integrated and well-managed use of these areas demands a closely knit, well co-ordinated, overall agency, vested with suitable powers to make decisions effectively, and with the wisdom of a Solomon, to boot.

In a series of far-reaching recommendations the MIT reports calls for: a national coastal zone policy to determine priorities for future uses and to maintain natural ecosystems; a coastal zone task force to develop management schemes and model guidelines for regional and local plans; for revision of legal institutions and procedures to make management more effective; for establishment of coastal zone centres to carry out and coordinate scientific, social and legal research programmes; for a national system of coastal area preserves with closely restricted access, to protect basic genetic stocks.

The problems exposed are those we face nearer home, the ideal solutions much the same as those we would choose: will the Americans be more successful than we in devising a fair, rational and effective scheme of regional control? The cards seem stacked against them: to quote: “67% of California's estuarine habitats lost in twenty years”; “of recreational shoreline, 92% was privately owned”; “booming coastal industry” which includes increased dredging and filling, increased developments in underwater mining and oil extraction.

UK problems of the coastal zone have been considered, in part, by the Royal Commission². The new Regional Water Authorities will be able to tackle some effects of our present disorganization, but will be short on skills and resources in the aquatic field, at least initially, as well as restricted in the scope of their interest. Surely the need is now for the UK to look at wider aspects of coastal zone management. The growing offshore extraction industries and our developing links with other riparian countries bordering coastal waters will present

many problems in the years ahead that a rational management scheme could overcome. Perhaps the Royal Commission could extend its sights beyond estuaries, to the coast and nearshore waters, to identify important issues and to achieve an overall assessment of our needs, both now and in the future.

The MIT report represents a rational and sensible approach to these problems, and no one sector has been able to press its own problems at the expense of the others. This, in essence, is the virtue of the openness and flexibility of the workshop approach. But the shining ideals and grand concepts need both the will, the machinery, and the funds to advance further. The provision of these, both in the UK and US, is where the real challenge lies.

G. HOWELLS

¹ "Resource Science: The nurture of an infant", *Bioscience*, 23, 13 (1973).

² Third Report of the Royal Commission on Environmental Pollution, Cmd 5054 (HMSO, 1972).

Activities of Wasps

The Wasps. By H. E. Evans and M. J. W. Eberhard. Pp. vi+265. (David and Charles: Newton Abbot, July 1973.) £3.65.

THE wasps are all those sting-bearing or aculeate Hymenoptera which are not ants or bees. About half of these are wasps in the more restricted sense—species which build nests and store food in them for their young. The ability to display this degree of maternal care involves many new behavioural traits; having a nest, for example, means having a sense of locality and a good memory and these in turn make such wasps a fascinating study because of the contrasts between some quasi-human behaviour and much rigid instinctive activity.

Dr Evans is an authority on the diggerwasps, a large group of solitary species on which he has published much original work. They show all stages from the simplest in which the wasp stores paralysed prey and lays an egg on it but then seals the cell to such species as *Amonophila pubescens* which brings her larva food as required, over several days, and is able to run two nests simultaneously, in different stages of development and requiring different treatment.

The other author, Dr Eberhard, has made brilliant studies of *Polistes* wasps. The colonies of these insects are very convenient for observation, the single combs being usually completely exposed, often hanging from the eaves of houses and the colonies being mostly small so that the individuals can all be marked with paint and their activities separately recorded. Species are found in both temperate and tropical climates and the

resulting differences in behaviour enable us to see better what elements are fundamental and what are adaptations to local conditions. Thus in temperate climates only the fertilized females survive the winter while the males and workers die. To survive, the female has to be rather larger and to lay down a fat reserve of a rather different form. In the spring she can found a new colony unaided until her first daughters emerge. In the tropics, colonies would be perennial except that, when the dominant egg-laying female begins to fail, the colony disperses, usually founding new colonies with swarms.

It is not yet certain that in such species there is any distinction between egg-laying female and workers except a behavioural one, the egg-laying female being able to prevent the others from laying, so that they become workers by default. In such wasps there is still need for research to settle whether there is a caste of real workers which could not alone found new colonies. The more advanced social wasps which are also described often make much larger nests with a beautiful and elaborate structure, inhabited by thousands of wasps which in some genera may include a large number of egg-layers. In these wasps the egg-layers are sometimes quite distinct and easily distinguishable from the workers to the naked eye, as in the British social wasps. All these and many other topics are ably and lucidly discussed in this valuable introduction.

O. W. RICHARDS

Motile Models

Motile Muscle and Cell Models. By N. I. Arronet. Translated from the Russian by Basil Haigh. (Studies in Soviet Science.) Pp. ix+192. (Consultants Bureau: New York and London, 1973.) \$29.

THE title of this unusual book may mislead the prospective reader. What constitutes a model of a muscle or motile cell? By a model one often means a physical object or a mathematical theory which reproduces the important properties of a more complex system. But in the present context, model is used in the sense of a copy of the original. In 1946 Varga in Szent-György's laboratory introduced the glycerol-extracted muscle fibre as a model of a living muscle. Treatment with glycerol destroys the cell membrane or greatly increases its permeability and removes metabolites and soluble enzymes. What remains is a working model of the muscle which can be manipulated by the experimentalist since it is permeable to substrates and inhibitors of the contractile proteins. Whether the properties of the model reproduce those of the living muscle must be determined by experiment.

Because the contractile proteins are relatively insoluble the model has proved to be a remarkable likeness of the original. Nevertheless there are differences, particularly in regard to inhibition of ATPase activity in the relaxed state.

The preparation of a glycerinated model is a simple technique, and has consequently been applied to a variety of presumed motile systems, including cilia, sperm, dividing cells, amoebae (and other organisms which exhibit protoplasmic streaming), myonemes of *Vorticella* mitochondria, and chloroplasts. The criterion for a successful model is simply the production of some form of movement on addition of ATP or other substrates. If the original is a highly ordered structure whose mechanical properties have been determined, one can establish that the model is a reasonable copy of the original. The technique has been successfully applied to cilia and flagella particularly by Gibbons who has obtained wave propagation and swimming movements with glycerinated sperm. For other systems it is difficult to decide whether the essential properties have been preserved and whether the response observed bears any relation to the normal function.

Arronet's book is a survey of studies on glycerinated models of all kinds. One use of models is for teaching purposes and perhaps the most interesting feature of this book is a collection of recipes for making models. Practical details are stressed and many of the methods seem to have been tested by the author.

The remainder of the book is a review of the literature on model studies. The presentation is more in the form of a recitation than a critical discussion. As long as the model is prepared from a muscle or cilium, one is on relatively firm ground, but for other systems extreme caution is required. Discussion of work on mitochondria and chloroplasts will serve as an example. Addition of ATP to these organelles, whether glycerinated or not, can lead to changes in shape and volume. The presence of a myosin-like contractile protein has been claimed and denied by a number of workers and at present it seems likely that the volume changes can be explained by ion movements. Yet Arronet concludes on the basis of ATP response of glycerinated mitochondria and chloroplasts that they "share a common mechanism of contraction with muscles, enzymatic interaction between the contractile protein and ATP".

Glycerinated models have been and will continue to be an important method in the study of motile systems. This book provides a useful collection of such studies and will serve as a valuable reference.

E. W. TAYLOR

CORRESPONDENCE

Smoking and Pregnancy

SIR,—Some of us decline to accept Dr Goldstein's own evaluation of his criticisms¹⁻³. He states³, as an "undisputed" fact, that "... the distribution of birthweights for babies of smokers is the same as that for non-smokers except that it is shifted downwards by about 170 g". (This is known as the 'displacement hypothesis'.) It follows that the mean birthweight of infants born to smoking mothers should also be "about 170 g" less than that for babies born to non-smoking mothers. In Yerushalmy's study⁴, the observed differences in the mean birthweights were 209.1 g for "whites" and 204.8 g for "blacks". By suitably stretching our imaginations we can, perhaps, regard these as being "about 170 g". However, Yerushalmy⁵ also tested the hypothesis that the distributions of low birthweights, allowing a displacement of 200 g between the smoking and non-smoking series, are the same. He found that the distributions differ significantly ($0.005 < P < 0.01$). The 'displacement hypothesis' is therefore rendered improbable by Yerushalmy's⁵ findings.

So much for "undisputed" facts. Apart from raising doubts about Goldstein's most confident assertions, they do not affect Yerushalmy's arguments. To quote Yerushalmy⁶, "... the major conclusions in the paper (ref. 4) do not rest on the results of the displacement hypothesis". In particular, contrasts between the findings for infants of smoking mothers and smoking fathers cannot easily be reconciled to a cause-effect hypothesis⁴. Although smoking mothers, and especially smoking fathers, had a higher incidence of low-birthweight babies than corresponding non-smokers, prognosis (death and congenital anomalies) for the low-birthweight babies of smoking fathers was much worse than for low-birthweight babies of smoking mothers⁴. By far the best prognosis was given for infants of matings in which the mother smoked and the father did not. This finding applied both to "whites" and "blacks". Furthermore, the general unsoundness of arguing from simple association to cause was emphasised by the large biological and mode-of-life differences demonstrated between smoking and non-smoking gravidas.

Now to answer Goldstein's second point³. Yerushalmy⁶ found that women who began to smoke after the birth of their baby had a much higher incidence ($\times 1.8$) of low-birthweight babies than those who did not take up smoking. His investigation was confined to all

births that occurred in women aged twenty-five or less, and in women who started to smoke in this age-range. Goldstein³ argues that the observed difference in the incidence of low-birthweight babies arises because mothers who started smoking before twenty-five years of age would have had their babies at an earlier age than those who did not take up smoking: younger mothers, he claims, have lighter babies. Yerushalmy⁷ has previously shown that his findings do not support this objection: "... within the limited range of ages under twenty-five years the variation in the proportion of low-birthweight infants is very small and could not account for the large differences found." He supported his argument with a table showing the mothers' age, total live births, and the numbers and incidence of low-birthweight infants⁷. We can split the age-range conveniently into two groups to give equal numbers (164) of low-birthweight infants: for mothers in the age-range fifteen to twenty-one years, the incidence of low-birthweight babies was 6.2% (164/2639); and for those in the age-range twenty-two to twenty-five it was 5.6% (164/2906). The small difference does not approach significance (χ^2 with Yates correction = 0.71; $0.3 < P < 0.5$). By contrast, the differences in the incidence of low-birthweight babies born to mothers in different smoking categories were large and significant. For "white" non-smokers, the incidence was 5.3%, but for "white" mothers who took up smoking after the birth of their baby it was 9.5% ($P < 0.01$)⁶. The corresponding incidence⁶ for mothers who smoked during pregnancy was 8.9%; and for those who gave up smoking after the birth of their baby it was 6.0%, similar to that for non-smokers. Trends for "blacks" resembled those for "whites", but because of smaller numbers, the only statistically significant difference was between those mothers who gave up smoking after the birth of their baby—with an incidence of low-birthweight babies of 13.4%—and those who smoked both during pregnancy and afterwards—with an incidence of 19.9% ($P < 0.02$). This collective evidence⁶ therefore fails to corroborate the causal hypothesis. Each of its features is remarkably consistent with the view that the smoker, rather than the smoking, is responsible for the high incidence of low-birthweight infants^{6,7}.

Finally, I return to the questions raised in your editorial of September 14. A news story based on an accurate

report of an article by Goldstein opened with the statement that cigarette smoking during pregnancy "caused the deaths of 1,500 babies in Britain last year". Under pressure from your leading article, Goldstein conceded in these columns, on October 5, "... the scientific evidence for a causal relationship may not be very conclusive". These dual standards raise important issues.

The public should be able to trust definitive statements made by scientists in their own field of expertise. If subsequently this trust proves to be unfounded, the credibility of scientists will be undermined, not only to their detriment, but to that of society at large.

Yours faithfully,

P. R. J. BURCH

SIR,—We join Professor Burch¹ in welcoming your leading editorial² on "smoking, pregnancy and publicity", and for noting that the elementary fallacy of inferring causality from statistical association is present in some reports that have received publicity.

In response to your editorial, Goldstein³ cites a *British Medical Journal* editorial⁴ that he states "suggests" validity of the smoking-causality hypothesis as an explanation for the statistical association between smoking behaviour of women and birth weights of their children. An alternative hypothesis, set forth by Professor Yerushalmy, is that the smoker rather than smoking influences birth weight⁵. Another expression of this hypothesis is that "smoking behaviour of women and birth weights of their children are influenced by a common cause ... the individual genotype or constitution"⁶. The *British Medical Journal* editorial⁴ does not merely suggest, but asserts that "no reasonable doubt now remains that smoking in pregnancy has adverse effects on the developing foetus". As we have noted⁶, the editorial overlooked

several reports that disagree, especially those of Yerushalmy.

Ross and colleagues⁷, and Goldstein⁸, deny having inferred causality from correlation. To the causal quotation cited in the *Nature* editorial² may be added their own assertion⁸, based on statistics, that "cigarette smoking during pregnancy increased the foetal plus neonatal mortality rate by 28% and reduced birth weight by 170 g. . . ." They also assert⁷ that the constitutional hypothesis as evaluated by Yerushalmy⁵ "suffers from severe methodological shortcomings, making it clearly untenable", citing a critique by Goldstein⁹. However, they neglect to mention Yerushalmy's rejoinder¹⁰ which, in effect, demolished this critique⁹.

Goldstein expressed his opinion that it would be "unethical" not to advise and encourage "pregnant women, especially 'high risk' ones, to stop smoking"¹³. In response to similar statements by Goldstein⁹, Yerushalmy¹⁰ commented, following a data analysis, that it would be unfortunate "to recommend a course of action based on conjectures, subjective notions, and easy explanations not supported by available data." The smoking-causality hypothesis to explain the association between smoking by women and birth weights of their children is incompatible with observed data^{5,6}. Such incompatibility, if confirmed independently, requires rejection of this hypothesis.

A problem arises since human smoking behavioural subgroups, for example, smokers, non-smokers and ex-smokers, are self-selected rather than randomly selected, and thus are biased samples. This introduces special problems for statistical testing of hypotheses^{5,6}. It is quite possible that for a subgroup of all smokers, tobacco use may be symptomatic of underlying

needs, perhaps arising in part from variations in biogenic amine physiology, that tend to be alleviated by nicotine^{6,11}. Cigarette smokers tend to adjust their smoking behaviours according to the nicotine content of cigarettes¹². Accordingly, ethological homeostatic mechanisms may be involved^{6,13}.

Goldstein cites animal studies in support of his position⁸. In addition to the usual caveat concerning inferences from experimental animal studies to man, based on interspecific physiological differences, there is a further problem. If habituated human smokers are on the average physiologically different from non-smokers, this difference may not be reflected in the physiology of experimental animals used in tests. Moreover, biogenic amine release in non-deficient test animals above homeostatic optimal ranges may be harmful¹⁴. The fallacy of typology¹⁵ may well be involved.

Consider the following observations: the negative association of carboxyhaemoglobin (COHb) levels of women with birthweights of their children¹⁶; the low COHb levels of some smokers^{16,17}, and the limited data for angina patients showing that high COHb levels of smokers are sustained during a non-smoking period¹⁸. These are compatible with a constitutional rather than a smoking-causality hypothesis. Such observations suggest caution regarding rejection of constitutional hypotheses and allegations that smoking-causality hypotheses concerning birth weight are in fact true. In this complex problem, available objective evidence for testing alternative hypotheses must be considered fairly, without overlooking critical reports that are detrimental to the smoking-causality hypothesis⁴, or to any other hypothesis. It is to be hoped that in any scientific problem all avail-

able objective evidence may be utilised, thus minimising the need for subjective judgment and opinion.

Yours faithfully,

APPOINTMENTS VACANT

UNIVERSITY OF DUNDEE

Lectureship in Biochemistry

(Department of Psychiatry)

Applications are invited for the above post, the occupant of which will have teaching duties in connection with the undergraduate and post-graduate courses run by the Department, and will be expected to undertake research, clinical or animal, on aspects of biochemistry relevant to medicine. Close functional links with the Department of Biochemistry (Professor P. B. Garland) have been arranged.

Salary scale: £1,929-£4,548, with placing according to qualifications and experience. FSSU; grant towards removal expenses.

Applications (6 copies, overseas applicants 1 copy) should quote Reference Est/73/73J, contain the names and addresses of three referees, and reach The Secretary, The University, Dundee DD1 4HN (from whom further particulars can be obtained) by December 7, 1973.

(1573)

FLINDERS UNIVERSITY OF SOUTH AUSTRALIA

SENIOR LECTURESHIPS/LECTURESHIPS

IN THE SCHOOL OF MEDICINE
HUMAN PHYSIOLOGY
HUMAN MORPHOLOGY
CLINICAL BIOCHEMISTRY

A new School of Medicine is being established as part of the FLINDERS MEDICAL CENTRE, a teaching hospital presently being constructed on a highly integrated curriculum is being planned for campus at the Flinders University of South Australia. The first 64 medical students that will enter the Centre in February, 1975. The Foundation Professors appointed thus far are PROFESSOR M. N. BERRY (Clinical Biochemistry), PROFESSOR A. W. ROGERS (Human Morphology) and PROFESSOR L. B. GEFFEN (Human Physiology). PROFESSOR G. J. FRAENKEL has been appointed as first Chairman and Dean of the School of Medicine.

Applications are now being invited for tenured lecturing appointments in the disciplines of HUMAN PHYSIOLOGY, HUMAN MORPHOLOGY and CLINICAL BIOCHEMISTRY. Applications are encouraged from candidates with clinical interests. Appointees will be expected to take up their positions by August 1974.

As in all other disciplines in the School of Medicine, suitably qualified appointees will have responsibilities in the areas of teaching research and clinical service. Appointees with medical qualifications registrable in South Australia may receive a clinical loading of up to \$A2,500 depending on the degree of clinical responsibility involved.

Present salary scales are: Senior Lecturer \$A12,268-\$A14,308; Lecturer \$A8,698-\$A11,982. Superannuation is on the FSSU basis.

Further information may be obtained from the Secretary-General, Association of Commonwealth Universities (Appis.), 36 Gordon Square, London WC1H 0PF. Applications should be lodged, in duplicate, with The Registrar, The Flinders University of South Australia, Bedford Park, South Australia, 5042, not later than December 21, 1973. (1626)

CSIRO AUSTRALIA

DIVISION OF RADIOPHYSICS, EPPING, N.S.W.

RESEARCH SCIENTISTS

GENERAL. The Division of Radiophysics of the Commonwealth Scientific and Industrial Research Organization operates the Australian National Radio Astronomy Observatory at Parkes, N.S.W., and the Solar Radio Astronomy Observatory at Culgoora, N.S.W. The Division offers outstanding opportunities for research in radio astronomy and associated development. These positions are available at the Division's headquarters in Epping, N.S.W.

Reference Number 780/521

FIELD: COSMIC RADIO ASTRONOMY

DUTIES. To pursue research in the field of cosmic radio astronomy.

QUALIFICATIONS. A Ph.D. degree in physics or mathematics, or equivalent qualifications, and demonstrable research ability, together with active research experience in some branch of radio astronomy.

Reference Number 780/522

FIELD: INSTRUMENTATION RESEARCH

DUTIES. To pursue basic theoretical and experimental research directed towards the development of new and improved low-noise receivers at very short wavelengths for the Parkes 64 metre telescope. Cryogenic techniques form an important part of this work. A Hewlett Packard network analyser is available as a design aid.

QUALIFICATIONS. A Ph.D. degree in engineering or physics and demonstrable research ability. Familiarity with the techniques of low-noise reception is essential and experience in computer-aided design would be an advantage.

Reference Number 780/523

FIELD: AERIAL DESIGN

DUTIES. To participate in a programme on advanced aerial systems. The appointee will participate primarily in basic theoretical and experimental research on electromagnetic problems associated with large focusing reflectors. However, an interest in all aerial techniques involved in the Division's radio astronomy and applied research programmes will be encouraged.

The Division is well equipped for aerial measurements over a wide range of micro wavelengths and has excellent computing facilities.

QUALIFICATIONS. A Ph.D. degree in engineering or physics and demonstrable research ability, together with a thorough background of electromagnetic theory and aerial and guided wave techniques. Practical experience in these fields would be an advantage.

SALARY. The appointments will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A8,489-\$A12,932 p.a. An outstanding applicant may be offered appointment at a higher level.

TENURE. Either an indefinite or fixed term appointments may be negotiated. Indefinite appointments carry Australian Government Superannuation benefits.

Applications, stating full personal and professional details, the names of at least two professional referees and quoting the appropriate Reference Number should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64-78 Kingsway, London WC2B 6BD.
by the 14th December, 1973.

Applications in U.S.A. and Canada should be sent to:

The Counsellor (Scientific),
Embassy of Australia, 1661 Massachusetts Avenue, N.W.,
Washington, D.C. 20036, U.S.A.

(1584)

ELECTRON MICROSCOPE TECHNICIAN Grade 3 required for Biological E.M. Unit containing 3 transmission and one scanning unit. Candidates with experience of scanning electron microscopy preferred. Day release available. Salary Grade 3 £1,650×54-£1,920 p.a. plus £175 p.a. London weighting. Five-day week, five weeks (in total) annual leave.—Letters only to Assistant Secretary (Establishment) (N), Queen Mary College, Mile End Road, London E1 4NS, stating age, experience and qualifications. (1540)

ROYAL POSTGRADUATE MEDICAL SCHOOL. SENIOR TECHNICIAN required in Department of Medicine. The appointee will assist in a research programme concerned with the detection of early bronchial disease by sensitive physiological tests. Qualifications HNC in physiological measurement or equivalent. Salary in range £1,473-£2,169 per annum, according to qualifications and experience.—Applications to the Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, DuCane Road, London W12 0HS, quoting reference 2/213/N. (1558)

BBC NATURAL HISTORY UNIT

requires

PRODUCTION AND RESEARCH ASSISTANTS

To work on a wide range of Natural History Television Programmes, initially the "World About Us".

Production Assistant, (Ref. 73.G.924N)

Will be required under direction to research, suggest and write treatments and help produce and direct film or studio programmes. Experience of television production and a knowledgeable interest in Natural History or Biology essential. Appropriate degree desirable. Based Bristol.

Salary: £3,123 p.a. (may be higher if qualifications exceptional) × £156 to £3,903 p.a. plus £195 p.a. non-day working allowance.

Research Assistants, (Ref. 73.G.923N)

Required to help with the research, content and writing of these programmes. Essential qualifications are a knowledge of film work and editing problems; the ability to work out story lines capable of visual illustration. Appropriate degree or knowledgeable interest in Natural History or Biology desirable. Based Bristol.

Research Assistant appointments will be made on contract for one year in the first instance.

Salary in the range £1,920-£2,130 p.a.

For all posts applicants must be prepared to make protracted overseas visits in rough conditions.

Write or telephone now for an application form (enclosing addressed foolscap envelope and quoting appropriate reference number) to

APPOINTMENTS DEPARTMENT, BBC,
LONDON W1A 1AA
Tel. 01-580 4468 ext. 4619

(1554)

Marine Biological Association of the United Kingdom

DIRECTOR

The Council of the Association will shortly proceed to the election of a Director of the Marine Biological Laboratory at Plymouth to take office on the retirement of Dr J. E. Smith, C.B.E., F.R.S., on 30th September, 1974. Those who wish their names to be considered are asked to inform the President

Sir Alan Hodgkin, O.M., P.R.S.,
Physiological Laboratory,
Downing Street, Cambridge CB2 3EG

not later than 19 December, 1973. The terms of the appointment will be arranged with the selected candidate.

(1535)

LINCOLN UNIVERSITY COLLEGE OF AGRICULTURE NEW ZEALAND

LECTURER/SENIOR LECTURER IN AGRICULTURAL METEOROLOGY

The Council of Lincoln College invites applications for appointment to the recently established position of Lecturer/Senior Lecturer in Agricultural Meteorology.

As this is the first College appointment in this field it is important that the appointee be able to communicate with agriculturalists and horticulturists as well as engineers and meteorologists.

Applicants should hold an appropriate degree and be capable of developing courses in Agricultural Meteorology and Climatology for degrees in Agriculture, Horticulture and Agricultural Engineering at undergraduate and postgraduate level.

Commencing salary according to qualifications and experience. The present salary scales for academic staff are: Lecturer \$NZ6,335-\$8,103; Senior Lecturer \$NZ8,249-\$9,723 (bar) \$10,019-\$10,606.

Removal expenses and fares of successful applicant will be reimbursed up to specified limits.

New Zealand Government Superannuation available. Conditions of appointment, giving further details of this position at Lincoln College, can be obtained from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University College.

Applications close on January 31, 1974. (1570)

UNIVERSITY OF THE WEST INDIES TRINIDAD

Applications are invited for (a) SENIOR LECTURESHIP or (b) LECTURESHIP IN AGRICULTURAL ENGINEERING in the Department of Crop Science. Applicants must possess a postgraduate qualification in agricultural engineering, preferably with particular reference to its application to soil and water. Experience in tropical crop production and design of farm buildings is considered highly desirable, though not essential. Salary scales (under review): (a) £2,700-£4,200 per annum, (b) £1,850-£3,265 per annum. Child allowance. F.S.S.U. Family passages; triennial study leave.

Detailed applications (6 copies), including a curriculum vitae and naming 3 referees, should be sent as soon as possible to the Secretary, University of the West Indies, St. Augustine, Trinidad. Further particulars of the post will be sent to all applicants. (1561)

UNIVERSITY OF SYDNEY LECTURESHIP IN GEOPHYSICS

Applications from suitably qualified scientists are invited for the above-mentioned position in the Department of Geology and Geophysics. The Department offers a senior course in Exploration Geophysics and the appointee will be expected to lecture in this course. However, the Department is developing research in marine geophysics and preference will be given to applicants with experience in this field. Applicants should be prepared to take up duties early in 1974.

The position advertised is permanent but in appropriate cases an initial three-year appointment may be made with possibility thereafter of permanency or in certain cases return fares.

Salary: \$A8,698-\$A11,982 p.a.

Applications, including curriculum vitae, list of publications and the names of three referees, by January 18, 1974, to the Registrar, University of Sydney, N.S.W. 2006, Australia, from whom further information is available. Information also available from Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF. (1627)

UNIVERSITY OF ADELAIDE POSTDOCTORAL FELLOW IN MARINE PLANT BIOLOGY

Applications are invited for the above-mentioned appointment in the Department of Botany, to undertake a study of the effect of sewage effluent outfalls on marine plants (seagrasses and marine algae) within St Vincent Gulf, near Adelaide, South Australia. The appointment which is financed by a grant from the Australian Research Grants Committee, is available for a period of two years from January 1, 1974, with possible extensions for a third year.

Applicants should have completed a doctoral degree in some aspect of marine ecology, and should be familiar with marine plants and their reproduction, as well as instruments used in environmental assessment. Scuba experience is essential.

Salary scale: \$A6,967-353(4)-\$8,379.

Application in duplicate, giving particulars of age, qualifications (including dates obtained) and the names and addresses of two referees, should be sent to the Registrar, The University of Adelaide, GPO Box 498, Adelaide, South Australia 5001, as soon as possible, and no later than December 31, 1973.

Further enquiries should be addressed to Dr H. B. S. Womersley, Department of Botany, The University of Adelaide. (1628)

Senior Animal Technician

We have an opening, with excellent prospects of advancement, for a Senior Animal Technician at our new Pharmaceutical Research Centre at Milton Keynes.

Candidates should have experience of the handling and care of experimental animals including dogs, and will have the opportunity to make a real contribution to our research programme. Candidates should also be Fellows or Associates of the Institute of Animal Technicians.

Pharmacologist or Veterinary Surgeon

To assist in the design and execution of experiments related to the pharmacokinetics of novel drugs, we require an experienced Pharmacologist or Veterinary Surgeon. The successful applicant should have demonstrated practical skills with experimental laboratory animals, including dogs, and should have the capability of developing his own lines of research related to furthering the understanding of the mechanism of action of new drugs.

Autoradiography

We are seeking a Senior Scientist to lead a small team to design and carry out Autoradiography studies as part of our pharmacokinetic programme on drugs under development at our new Research Laboratories at Milton Keynes.

The person we seek will have experience in wholebody autoradiography and should be familiar with histological techniques. He, or she, should be capable of appreciating and developing the potentialities of autoradiography, particularly in its application to dynamics of pharmaceuticals.

Attractive salaries will be offered. The company also operates a merit bonus scheme, a contributory pension scheme and free membership for employees and dependants of the PPP Health Scheme. Assistance with house removal may also be available if required.

Would candidates, in the first instance, please write with fullest possible details to:

Personnel Officer,
Pharmaceutical Division,
Hoechst UK Limited,
Hoechst House,
Salisbury Road,
Hounslow, Middx.
Tel: 01-570 7712 ext. 3082

(1542)

STERLING-WINTHROP

GROUP

Sterling-Winthrop Group Medical Services is comprised of four departments which offer a medical and technical information service to all divisions within the Group. Sterling-Winthrop Group Ltd. is mainly comprised of several pharmaceutical companies concerned with the production and selling of ethical and over-the-counter medicines and household products. Conditions of service include a 36½ hour week, finishing at 4.00 p.m. on Fridays, a subsidised restaurant, 3 weeks' holiday increasing to 4 weeks' after one year's service, a sports and social club, and a contributory pension scheme. We now have two vacancies:

Technical Translator

Translations Department

A recent graduate with French to Honours Degree standard and German subsidiary is needed. Knowledge of a Scandinavian language and/or Spanish and/or Italian is a definite advantage. Duties will involve translation into English of medical and pharmacological reports and a wide variety of other material such as is required by an international pharmaceutical company. Training will be given to develop medical knowledge and terminology.

Medical Information Scientist

Technical Documentation Department

This small but vital department is responsible for the monitoring and evaluation of medical information relating to the development, marketing and promotion of the Group's ethical and proprietary products. Duties are varied and interesting including answering of enquiries and preparation of technical reports. Applicants should recently have obtained a degree or equivalent in a biological science. Previous experience in information work could be useful but is not essential.

Write for an application form and further details to:

Mrs. Hazel R. Lane, B.Sc., F.I.S., D.M.S., Controller, Group Medical Services,
Sterling-Winthrop Group Ltd., Winthrop House, Surbiton-on-Thames, Surrey

WINTHROP

(1602)

Glaxo Holdings Limited

Young Science Graduate *to work as a* Registration Officer

in the New Product Services Division based in Islington. The work involves the registration of Company products in specified overseas countries in which Glaxo Holdings Ltd. has a commercial interest. This entails the preparation of appropriate documents, editing submissions from within the Company before transmitting them overseas, dealing with queries and raising arguments in support of our submissions for presentation to overseas registration authorities, etc.

Applicants of either sex should hold a degree, preferably in the physical or biological sciences, and be within the age range 20-25 years. The Company offers full training, a salary in the range £1680-£1800 p.a. plus an opportunity to participate in the Company's profits. Fringe benefits are those which would be expected of a Company of international size.

Please write to or 'phone for an application form: Miss D. Packman, Personnel Department, Glaxo Holdings Ltd., Graham Street, London, N1 8JZ. Tel: 01-253 3060.

(1579)

UNIVERSITY OF LEICESTER DEPARTMENT OF PHYSIOLOGY SENIOR LECTURER

Applications are invited for the post of SENIOR LECTURER in the Department of Physiology (Head of Department, Professor R. Whittam, F.R.S.). Experience and an interest in teaching medical students are essential. Preference will be given to holders of a medical qualification, but other suitably qualified applicants will be seriously considered. There are excellent research facilities.

Initial salary, dependent on qualifications and experience, within the scale £4,368 to £5,496 a year, with F.S.S.U. membership.

Further particulars from the Registrar, to whom applications should be sent by December 11. (1423)

ARC ANIMAL BREEDING RESEARCH ORGANISATION

A vacancy arises of a research post concerned with studies of genetic control of mineral metabolism and of variation in production of ruminants. The work is relevant to animal breeding, nutrition and health. Candidates must have a good honours degree, with preferably postgraduate experience, a statistical aptitude and experience in data analysis. Appointment will be in the S.O./S.S.O. range (£1,318-£3,640) with FSSU.

Applications, with curriculum vitae and names of two referees, to the Secretary, ARC Animal Breeding Research Organisation, West Mains Road, Edinburgh EH9 3JQ. (1548)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the following vacancy:

POSTDOCTORAL FELLOW in the DEPARTMENT OF BIOCHEMISTRY

Salary Range: £1,764 × 159 × 156—£2,079; Duties to commence January 1, 1974, or as soon as possible thereafter. Closing date for applications December 10, 1973.

Applications, together with the names and addresses of two referees, should be forwarded to The Registrar, University College, P.O. Box 78, Cardiff, CF1 1XL, from whom further particulars will be available. Please quote 0941. (1544)

THE PUBLIC HEALTH LABORATORY SERVICE

requires

A SCIENTIST

to work at the MICROBIOLOGICAL RESEARCH ESTABLISHMENT, Porton Down, Salisbury, Wilts, to assist in an investigation of cell culture techniques for diagnosis of viral diseases.

The Appointment will be for 2 years in the first instance, subject to N.H.S. conditions of service and within the scale £1,278 to £1,980 (salary scale under review).

Apply with curriculum vitae to the Director, Microbiological Research Establishment by November 30, 1973. (1637)

QUEEN MARY COLLEGE UNIVERSITY OF LONDON

THEORETICAL PHYSICS

Applications are invited for a LECTURESHIP tenable from October 1, 1974. Preference will be given to candidates with interests in elementary particles or field theory. Salary scale £1,929-£4,548 p.a. plus £162 London Allowance. FSSU membership.

Applications are also invited for a RESEARCH FELLOWSHIP tenable from the same date, from candidates with interests in elementary particles or field theory. Salary scale £1,929-£2,553 p.a. plus £162 London Allowance.

Application forms available from The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS, to be returned by January 7, 1974. Candidates overseas should ask their referees to write directly. (1534)

UNIVERSITY OF DURHAM DEPARTMENT OF PHYSICS

Applications are invited for the post of SENIOR DEMONSTRATOR in the Department of Physics from January 1, 1974, for two years in the first instance with possible renewal for a third and final year. The Demonstrator will be expected to carry out research in one of the following fields: Cosmic Rays, High Energy Nuclear Physics, Magnetism, Nuclear Instrumentation, Optical Astronomy.

The salary will be on the scale £1,719-£2,613 per annum with FSSU benefits.

Applications (3 copies) including the names and addresses of three referees should be sent by November 26, 1973, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (1530)

UNIVERSITY OF MALAWI

BUNDA COLLEGE OF AGRICULTURE

Applications are invited for LECTURESHIP IN STATISTICS/MATHEMATICS, tenable as soon as possible. Applicants should have a degree in Statistics or equivalent qualifications or experience. The major responsibility will be to teach statistics to Degree and Diploma students. The post could be filled by a biometician or a statistician with an interest in teaching Mathematics. In the latter case, there would be an opportunity to teach Mathematics at both diploma and degree levels. Salary scale (including expatriate addition): £1,340-£2,250 p.a. plus either a University addition of £360 p.a. (taxable in Malawi) or supplementation (normally tax free) in appropriate case by the British Government, in range £600-£850 p.a. (if married) or £300-£550 p.a. (if single). The British Government may also provide children's education allowances and holiday visit passages. Gratuity: superannuation scheme transferable with FSSU; family passages; various allowances; biennial overseas leave; housing.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be forwarded by air mail, not later than December 17, 1973, to the Registrar, University of Malawi, University Office, PO Box 278, Zomba, Malawi. Applicants resident in UK should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further particulars may be obtained from either address. (1635)

UNIVERSITY OF OXFORD

There will be a vacancy for a POSTDOCTORAL BIOCHEMIST or MICROBIOLOGIST to work on bacterial sporulation. The appointment which will be for one year in the first instance, at an initial stipend of £1,821, may be extended for a further period of two years and there is provision for FSSU or its equivalent.

Applications, which should include relevant details and the names of two referees, should be sent before February 1, 1974, to Professor J. Mandelstam, Microbiology Unit, Department of Biochemistry, South Parks Road, Oxford. (1555)

UNIVERSITY OF
THE WITWATERSRAND
JOHANNESBURG, SOUTH AFRICASENIOR LECTURER/LECTURER
IN ZOOLOGY

Applications are invited for appointment to the above vacancy in the Department of Zoology. Duties are to be assumed as soon as possible.

Salary will be in the following ranges:

Senior Lecturer: R7,245-R9,315 (£4,330-£5,635 approx.);

Lecturer: R5,520-R7,935 (£3,350-£4,800 approx.).

The initial salary will be determined according to qualifications and experience. Benefits include an annual bonus, pension and medical aid facilities, and a housing subsidy, if eligible.

Intending applicants should obtain the information sheet relating to this post from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa with whom applications should be lodged not later than December 31, 1973. The information sheet may also be obtained from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1, with whom a copy of the application should be lodged. (1568)

UNIVERSITY OF IBADAN
NIGERIA

Applications are invited for LECTURESHIP IN GENETICS IN DEPARTMENT OF AGRICULTURAL BIOLOGY. Applicants should have a good background in Botany, Zoology or Applied Biology and postgraduate qualifications and experience in Genetics, Cytogenetics or Plant Breeding. Relevant teaching, research and curriculum development experience in a university will be an advantage as appointee will be expected to take an active part in teaching in both the undergraduate honours and postgraduate schools and in an integrated research programme in crop improvement and crop protection aspects of Agricultural Biology. Salary scale: N2,760-N4,830 p.a. (£1 sterling=N1.59.) The British Expatriates Supplementation Scheme is unlikely to be applied to this appointment. FSSU. Family passages; various allowances; regular overseas leave.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail not later than December 14, 1973, to the Registrar, University of Ibadan, Ibadan, Nigeria. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (1571)

Department of Trade & Industry
Warren Spring Laboratory, Stevenage

Applied Rheologist

- Fundamental work on rheology and instrumentation to measure complex material properties ■ Application to industrial operations.
- ☐ Experience in the rheology of non-Newtonian fluids, slurries and pastes
- ☐ Ref: SA/11/MF.

Chemist/Physicist/
Engineer

- Install and operate air pollution monitoring equipment ■ Carry out quality control ■ Analyse and interpret data.
- ☐ Ref: SA/13/MF.
- ☐ For both posts, appointment as Scientific Officer ☐ Degree/HND/HNC in appropriate subject.

Chemist/Physicist

- X-ray powder diffraction work - phase analysis and characterisation of catalysts ■ Equipment partly computer controlled.
- ☐ Appointment as Higher Scientific Officer or Scientific Officer ☐ Degree/HND/HNC in a physical science ☐ Experience of X-ray diffraction procedures and in computing an advantage ☐ Ref: SA/12/MF.

Salary: HSO £2076-£2667, SO £1318-£2177.

Age: HSO under 30, SO under 27.

For HSO appointments, candidates must have at least 2 years relevant post-graduate experience.

- ☐ Application forms (for return by 7 December 1973) from The Director, Warren Spring Laboratory, Elder Way, Stevenage, Herts.

group**
CIVIL SERVICE

(1603)

WELSH OFFICE — Y SWYDDFA GYMREIG

Scientific Adviser
Health Services

£5550

This is a new appointment in Cardiff with overall responsibility for improving the effectiveness of scientific and technical aspects of the reorganised health services in Wales, and for advising on the implementation in Wales of the Zuckerman report.

Main duties will be: to interpret and contribute to policy; liaise with the DHSS and maintain two-way links with area health authorities and hospitals; advise on scientific services and staffing in the health service; plan vocational education and training of scientific and technical staff at all levels; some liaison on purchasing arrangements for scientific and technical equipment including questions of standardisation and variety reduction.

This key post calls for candidates, probably from 35 to 50 who hold a 1st or 2nd class honours degree, or an equivalent qualification, in a relevant subject. Success as an administrator and communicator essential.

Starting salary as shown. Annual increments to £6460. Non-contributory pension scheme. Promotion opportunities not confined to the Welsh Office.

Full details of this appointment may be obtained by writing to the Civil Service Commission, Alencon Link, Basingstoke, Hants., RG21 1JB, or by telephoning BASINGSTOKE 29222 ext. 500 or LONDON 01-839 1992 (24-hour answering service), quoting S/8440/U.

Closing date 6 December 1973.

(1597)

Research Assistants

Beecham Research Laboratories, Medicinal Research Centre, Harlow will shortly open a new purpose-built toxicology block which will considerably increase facilities for toxicological and drug safety assessment.

This expansion has created openings for technicians at all levels who are keen to do an important job well and to develop their practical skills and theoretical knowledge.

Animal Studies

We have a senior opening for someone with experience in drug safety and toxicology procedures in a pharmaceutical or university laboratory. Other essentials are experience handling experimental animals and the ability to lead junior staff.

We also have a number of junior posts for young men and women (aged 18-25) who have a minimum ONC or 5 'O' level qualifications—the latter to include Biology, Chemistry and Maths. Willingness to work with experimental animals is essential.

Haematology

This is a trainee post for someone with at least 5 'O' levels including Biology and Maths or an ONC. No previous experience is required and training will be given in haematological techniques. Age 17-20.

Clinical Chemistry

We have two senior vacancies for those with experience of clinical chemistry techniques, which could have been gained in either a pharmaceutical laboratory studying drug safety and toxicology or in a hospital pathology department. Age 20-30.

There are also more junior appointments for those aged 17-25 who have a minimum qualification of ONC or 5 'O' levels—the latter to include Chemistry, Physics and Maths.

Histology

We have openings for senior technicians to share in the interesting and varied work of the Pathology section. Experience in general histological techniques is essential and this could have been gained in a pharmaceutical company or in a hospital pathology laboratory. Candidates are likely to possess an HNC or AILMT.

Starting salaries will be competitive and there are the usual fringe benefits associated with a large and expanding company. The Medicinal Research Centre is located near the Herts/Essex border and combines the facilities of a new town with proximity to London and pleasant surrounding countryside.

Please write, outlining your career to date, to
John Atkinson, Personnel Officer,
Beecham Research Laboratories,
Fourth Avenue, The Pinnacles,
Harlow, Essex.

(1547)

THE QUEEN'S UNIVERSITY OF BELFAST

Lectureship in Physiology

Applications are invited for a Lectureship in the Department of Physiology from January 1, 1974, or such other date as may be arranged. The successful applicant should have had experience in using histological techniques for research purposes and will assist in the teaching of histology to medical, dental and science students. The salary will be in the range £2,553-£4,548 but in certain circumstances may rise to £5,496. If medically qualified, the successful applicant may be paid an additional salary on a sessional basis by the Eastern Health and Social Services Board for hospital services undertaken over and above University duties. Both salaries carry contributory pension rights under the FSSU. The initial placing will depend on qualifications and experience.

Applications should be received by December 3, 1973. Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN. (Please quote Ref. 73/N.) (1574)

UNIVERSITY OF DAR ES SALAAM TANZANIA

Applications are invited for (a) SENIOR LECTURESHIP or (b) LECTURESHIP IN AGRICULTURAL BOTANY in Department of Crop Science. Applicants should have a good honours degree in Botany, Agricultural Botany, or Agriculture, plus a higher degree and/or research experience in Botany or Agricultural Botany. Appointee will be required to teach Agricultural Botany, including Ecology and Agro-meteorology to undergraduates. He will also be expected to carry out research in his field of speciality and supervise postgraduates. Salary scales: (a) T£2,380-T£2,800 p.a. (b) T£1,898-T£2,318 p.a. (T£1=£1.18 sterling.) The British Government may supplement salary in range £550-£950 p.a. (sterling) for married appointee or £300-£650 p.a. (sterling) for single appointee and provide children's education allowances and holiday visit passages. FSSU. Family passages; biennial overseas leave.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be forwarded by air mail not later than December 17, 1973, to the Chief Academic Officer, University of Dar es Salaam, P.O. Box 35091, Dar es Salaam, Tanzania. Applicants resident in UK should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (1633)

UNIVERSITY OF DAR ES SALAAM TANZANIA

Applications are invited for (a) SENIOR LECTURESHIP or (b) LECTURESHIP IN SCIENCE EDUCATION (CHEMISTRY) in Department of Education. Applicants must have a good first degree in Science, including Chemistry. Preference will be given to those holding a higher degree. Appointee must have had some teaching experience at secondary level and must be acquainted with modern approaches to the teaching of Chemistry. He will be expected to teach Chemistry Methods to undergraduates; to conduct research in his area of specialisation; to assist with seminars in the more general areas of education and to participate in teaching practice supervision. Salary scales: (a) T£2,380-T£2,800 p.a. (b) T£1,898-T£2,318 p.a. (T£1=£1.18 sterling.) The British Government may supplement salary in range £550-£950 p.a. (sterling) for married appointee or £300-£650 p.a. (sterling) for single appointee (normally free of all tax) and provide children's education allowances and holiday visit passages. FSSU. Family passages; biennial overseas leave.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than December 17, 1973, to the Chief Academic Officer, University of Dar es Salaam, P.O. Box 35091, Dar es Salaam, Tanzania. Applicants resident in UK should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars of this appointment may be obtained from either address. (1634)

UNIVERSITY COLLEGE OF WALES
WELSH PLANT BREEDING STATION
APPOINTMENT OF
LIAISON OFFICER

Applications are invited from suitably qualified and experienced persons for a post as member of the Liaison Unit at the Station.

The salary range is £3,472 to £4,575 per annum and the commencing salary will be determined in the light of the successful applicant's qualifications and experience. The post is superannuated under FSSU.

The appointment is one of high responsibility and the successful applicant will be expected to undertake a wide range of duties associated with communicating the findings of research. It is expected that the successful candidate will have a scientific training and/or experience in the Public Relations field, with practical knowledge of the agricultural industry.

Full details may be obtained from the Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, Cards. SY23 3EB, to whom applications, together with the names of two referees, should be made by letter on or before November 30, 1973. (1565)

AGRICULTURAL RESEARCH
COUNCIL

has a vacancy for an ENTOMOLOGIST or a BIOLOGIST with entomological experience to take charge of the insectary in the Unit of Invertebrate Chemistry and Physiology at the University of Sussex. The successful applicant will be expected to be responsible for rearing insects for hormone bioassay, toxicity testing and biochemical research. Two full-time assistants are provided.

Appointment will be made in the Scientific Officer (£1,318-£2,177 p.a.) or Higher Scientific Officer (£2,076-£2,667 p.a.) grade, depending on qualifications and experience. Superannuation, with allowance to off-set contributions.

Minimum qualifications: pass degree, HNC or equivalent. At least five years' post-qualifying experience is required for appointment to the higher grade.

Preference will be given to candidates with experience of rearing insects for experimental purposes.

Applications should be made in writing to:

The Secretary,
ARC Unit of Invertebrate Chemistry and
Physiology,
The University of Sussex,
Falmer, Brighton, Sussex,
BN1 9QJ. (1566)

McMASTER UNIVERSITY
VIROLOGIST

A position is available for a Virologist at the Assistant or Associate Professor level. The appointee will be part of a viral oncology group being formed at McMaster University as well as a member of the Department of Biology. His/her research interests should be the molecular biology and/or genetics of animal viruses. His/her primary responsibility will be research and supervision of graduate students.

Applicants should send their curricula vitae and the names of three referees to the Chairman, Department of Biology, McMaster University, Hamilton, Ontario L8S 4K1, Canada, to arrive no later than January 15, 1974. (1581)

CAVENDISH MEDICAL CENTRE

A vacancy exists in the above Health Screening Centre for a CLINICAL BIOCHEMIST. This is an interesting post with good working conditions. Salary negotiable, commensurate with experience.

Applications to Mrs Payne, 99 New Cavendish Street, London W1. (1529)

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF APPLIED MICROBIOLOGY
TECHNICIAN—Grade 5

required for a period of two years, to work on a project concerned with the study of genetic changes in yeast during continuous culture. This work is supported by a SRC research grant. Candidates should have H.N.C. or degree, or equivalent in microbiology or related sciences.

Salary scale: Technician Grade 5, £2,007 to £2,382 per annum.

Applications in writing, quoting reference AM.55, giving details of age, experience and qualifications to The Personnel Officer, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW. (1600)

MEDICAL RESEARCH COUNCIL
JUNIOR TECHNICAL OFFICER

A Junior Technical Officer is required to assist a scientist with research in nucleic acid and protein synthesis in mammalian cells. Applicants should have a degree or H.N.C. in Biochemistry, Chemistry and Biology. Salary will depend upon age and experience on a scale rising to £2,073.

Applications in writing to the Administrative Officer, Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh 4, by November 30, 1973. (1601)

CSIRO
AUSTRALIA

DIVISION OF ANIMAL PHYSIOLOGY, PROSPECT, N.S.W.

RESEARCH SCIENTIST

FIELD:

ENDOCRINOLOGY

GENERAL. The Ian Clunies Ross Animal Research Laboratory is the headquarters of the Division of Animal Physiology of the Commonwealth Scientific and Industrial Research Organization, and is situated at Prospect, 20 miles west of Sydney, N.S.W. The Laboratory has a total staff of 150, including 55 professional scientists. Past and current research of the Laboratory includes work on endocrinology, nutrition, reproduction and lipid metabolism.

The Laboratory is continuing a programme of research on endocrinology in relation to growth and nutrition. An endocrinologist is required to collaborate with other endocrinologists and nutritionists on this programme of hormonal regulation of production in domestic animals.

DUTIES. To conduct research into the control of hormone secretion by diet and hormonal regulation of protein metabolism, fat metabolism, appetite, body growth, or wool growth.

QUALIFICATIONS. A Ph.D. degree or equivalent qualifications supported by demonstrable research ability. Experience in endocrinology related to steroids, polypeptide hormones or prostaglandins and the immunoassay of hormones would be an advantage.

SALARY. The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A8,489-\$A12,932 p.a. An outstanding applicant may be offered appointment at a higher level.

TENURE. Either an indefinite or a fixed term appointment may be negotiated. An indefinite appointment carries Australian Government Superannuation benefits.

Applications, stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 245/561 should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64-78 Kingsway, London, WC2B 6BD.
by the 14th December, 1973.

Applications in U.S.A. and Canada should be sent to:

The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
Washington, D.C. 20036, U.S.A.

(1583)

MONASH UNIVERSITY
MELBOURNE, AUSTRALIA
CHAIR IN ZOOLOGY

A second professorship in Zoology has recently been established. Applications are invited from zoologists whose research interests coincide with one of the following established areas in the department: ecology, comparative physiology, developmental biology, and behaviour. The Department of Zoology comprises fourteen academic staff with supporting technical officers and is well equipped to conduct research and teaching in the above-mentioned fields. It is expected the appointee will assume duties in late 1974 or early 1975.

Further information concerning the Department is available from the Chairman, Professor J. W. Warren, in the University.

Salary: \$A19,102 per annum. Superannuation is based on an endowment assurance scheme, the employee and employer contributing 5% and 10% respectively.

Information on application procedure and further particulars may be obtained from the Academic Registrar, Monash University, Clayton, Victoria 3168, Australia, or the Secretary-General, Association of Commonwealth Universities (Appis.), 36 Gordon Square, London WC1H 0PF.

Applications should reach the Academic Registrar not later than January 11, 1974. The Council reserves the right to make no appointment or to appoint by invitation at any stage. (1624)

NATIONAL INSTITUTE FOR
RESEARCH IN DAIRYING
(UNIVERSITY OF READING)
BACTERIOLOGY DEPARTMENT

A SUPERVISOR is required for a section responsible for preparation of bacteriological media. Applicants should have had sound training in chemistry or bacteriology.

An appropriate degree, H.N.D., H.N.C., or equivalent is required. The appointment will be in the Scientific Officer grade within a scale of £1,318 to £2,177 per annum according to qualifications and experience. Superannuation, with an allowance to offset contributions. Apply on forms obtainable from the Secretary, National Institute for Research in Dairying, Shinfield, Reading RG2 9AT. Quote reference 73/46. (1471)

CHAIRMAN—DEPARTMENT OF
ANATOMY

Columbia University, College of Physicians and Surgeons, an equal opportunity employer, is seeking an individual as Chairman of Anatomy Department. Should be qualified medical scientist and experienced medical educator.

Send curriculum vitae to: Myron Winick, M.D., Chairman, Search Committee, Institute of Human Nutrition, 511 West 166th Street, New York, New York 10032. (1289)

VRIJE UNIVERSITEIT AMSTERDAM

Applications are invited for the position of

hydrologist

in the Hydrology Program of the Institute of Earth Sciences. Appointment commences January 1st '74. Candidates should be experienced hydrologists with a math.-physics background, preferably Ph.D., Dutch nationality preferred.

Duties:

teaching of surface water hydrology at graduate level in the laboratory and in the field in co-operation with the present faculty group, some additional undergraduate teaching in hydrology.

Submit inquiries to Dr. G. B. Engelen, Chairman Hydrology Program, Institute of Earth Sciences, 1085 De Boelelaan, Amsterdam, Netherlands.

Candidates are expected to be in agreement with the Christian principles of the Free University.

Applications should be sent to Hoofdafdeling Personeelszaken, P.O. Box 7161, Amsterdam.

(1541)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR DEPARTMENT OF APPLIED ZOOLOGY RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant in the above Department, to work under Dr J. M. Cherrett on the development of baits against tropical leaf-cutting ants. The main work will involve behavioural, chemical and developmental studies on laboratory colonies.

Applicants should have a good honours degree in Zoology, or in a closely related subject, and preference will be given to applicants with research experience in the general field of animal behaviour.

Starting salary will be £1,326 per annum and the initial appointment will be for one year commencing on January 1, 1974, with a possibility of renewal by mutual consent.

Applications (two copies) with full details of age, qualifications and experience, together with the names and addresses of two referees, should be sent not later than November 30, 1973, to the Secretary and Registrar, University College of North Wales, Bangor, from whom further particulars may be obtained.

(1531)

BEHAVIOURAL BIOLOGIST

The University of Chicago's Department of Biology invites applications for a faculty appointment in the area of behavioural biology. The University is an equal opportunity employer. Selection will be made on the basis of excellence and vigour in research and teaching. Applicants should forward the following material by December 31, 1973: (i) a curriculum vitae, including bibliography and reprints; (ii) names, addresses and telephone numbers of five references, and (iii) a summary, not to exceed two typed pages, of your current research plans and long-term goals. Material should be sent to Professor Hewson Swift, Chairman, Department of Biology, The University of Chicago, Chicago, Illinois 60637.

(1562)

HAMPSHIRE RIVER AUTHORITY ASSISTANT FISHERIES OFFICER DEPARTMENT OF TECHNICAL SERVICES £2,235-£2,820 p.a.

This is a new post to assist the Fisheries Officer in the operation of the Authority's Fishery functions. The successful applicant will be particularly responsible for developing a fisheries sampling programme to monitor the various fisheries. The Rivers Test and Itchen, important game fishing rivers, are contained within the Authority's area.

Applicants should hold a degree in a biological subject, preferably zoology, with some specialist training or experience in freshwater fisheries. The commencing salary will be related to qualifications and experience.

Further details and application forms are available from the Chief Administrative Officer, Hampshire River Authority, Eastleigh House, Market Street, Eastleigh, Telephone Eastleigh 7444, extension 48. Closing date for applications is December 10. Please quote reference SE2363/U.

(1546)

UNIVERSITY OF NEW SOUTH WALES SCHOOL OF MATHEMATICS, LECTURER

Salary: \$A8,698 range \$A11,982 per annum. Commencing salary according to qualifications and experience.

In the field of mathematical statistics. High academic qualifications required, together with research experience in statistics and/or probability theory; teaching experience in these areas advantageous.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Appis.), 36 Gordon Square, London, WC1H 0PF. Applications close in Australia and London on December 14, 1973.

(1551)

UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY

TECHNICIAN (GRADE 5)

(REF.: CH/453/AI)

required in the Department of Chemistry to join a team engaged on interesting work in organic chemistry. A knowledge of chemical theory to H.N.C. level is desirable, but the requirements of the post place greater emphasis on practical ability in preparative chemistry. The post will give the successful candidate the opportunity to learn special techniques used in the work, and to further his theoretical background.

Salary within the scale £2,007 to £2,382 per annum. Requests for application forms, quoting reference number, should be addressed to the Registrar, U.M.I.S.T., Sackville Street, Manchester M60 1QD, to be returned no later than November 28, 1973.

(1592)

CHELSEA COLLEGE UNIVERSITY OF LONDON

TECHNICIAN GRADE 2A required in the Microbiology Section of the Biological Sciences Group. Duties will include assisting in the preparation of media, reagents and cultures for undergraduate teaching and postgraduate research activities. Previous experience in Microbiology (bacteriology, mycology, virology) is required. Salary scale: £1,552 to £1,822 per annum (including London Allowance).

Application forms from Mr K. Harris (N), Department of Applied Biology, Chelsea College, Hortensia Road, London SW10 0QX.

(1590)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the following posts in the FACULTY OF VETERINARY SCIENCE:

1. SENIOR LECTURER IN DEPARTMENT OF VETERINARY PATHOLOGY AND MICROBIOLOGY. Applicants should be Veterinarians with a Ph.D. in Pathology or equivalent backed by considerable experience in research or teaching in Veterinary Pathology or animal diseases. Appointee will be required to assume responsibilities for lecturing and practicals in general systematic pathology and disease description course for undergraduate veterinary students and participate in research, tuition of graduates and routine diagnosis.

2. LECTURER IN DEPARTMENT OF PUBLIC HEALTH, PHARMACOLOGY AND TOXICOLOGY. Applicants should be Veterinarians with postgraduate training of either a Masters degree or a Diploma in Meat and Food Hygiene. Experience in organisation and working in slaughter houses would be an advantage.

Salary scales: (a) K£2,256 to K£3,036 per annum; (b) K£1,500 to K£2,580 per annum (K£1=£1.18 sterling). The British Government may supplement salaries in range £450 to £950 per annum (sterling) for married appointees or £150 to £650 per annum (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. F.S.S.U. Family passages; various allowances.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be forwarded by air mail, not later than December 14, 1973, to the Registrar, University of Nairobi, P.O. Box 30197, Kenya. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars of these appointments are obtainable from either address.

(1589)

BRITISH ANTARCTIC SURVEY SCIENTIFIC OFFICER

Applications are invited for the post of Biological Assistant to work in the Huntingdon/Cambridge area. The duties of the post may include:

- Operation of OHN analyser and bomb calorimeter.
- Operation of liquid scintillation counter.
- Preparation of histological sections, moss core sections and photomicrography.
- Analysis of microclimate records.
- Maintenance of cultures.
- Routine sorting and counting of samples.

QUALIFICATIONS

Candidates should be under 27 years of age with a degree or equivalent in a relevant subject.

SALARY SCALE

£1,318 to £2,177. Starting pay according to qualifications and relevant experience.

Application forms may be obtained from The British Antarctic Survey, 30 Gillingham Street, London SW1V 1HY.

Closing date: November 30, 1973.

NATURAL ENVIRONMENT RESEARCH COUNCIL

(1598)

TECHNICIAN

at

The Open University

The Materials Science and Engineering Mechanics Disciplines of the Faculty of Technology require a Technician to assist the staff of the Faculty in scientific research and laboratory work associated with television, visual aids and kits of experimental apparatus for students' use in their own homes.

Candidates are expected to have an ONC/HNC or equivalent qualification in metallurgy and/or mechanical engineering, with at least four years' experience. Candidates from allied engineering backgrounds will also be considered.

Salary, according to age, experience and qualifications, will be within the scale: £1,848-£2,163 per annum, with superannuation benefits.

Application forms and further particulars are available from **The Acting Personnel Manager, The Open University (EM2)**, P.O. Box 75, Walton Hall, Milton Keynes, MK7 6AL. Closing date: Friday, 30th November, 1973.

(1569)

THE UNIVERSITY OF LEEDS.

DEPARTMENT OF PLANT SCIENCES

TWO RESEARCH ASSISTANTS are required for a project to investigate the effects of nutrient and fertiliser salts on crop plants during the early stages of development, in relation to environmental variables. The posts would suit holders of degrees in botany, soil science or agricultural science, with an interest in crop nutrition or plant physiology. Salary on the scale £1,449 to £1,818.

Forms of application and further particulars from the Registrar, The University, Leeds LS2 9JT (please quote 41A/7/D). Closing date November 30, 1973. (1585)

NORTHERN REGIONAL HOSPITAL BOARD (SCOTLAND)

Applications are invited for the newly established post of BASIC GRADE BIOLOGIST (Graduate) in the Pathology Department of the Regional Hospital Board's Laboratories at Inverness. If possible prospective candidates should have special experience in cancer chemotherapy screening and/or tumour immunology. Salary in accordance with Whitley Council agreements.

Further particulars and forms of application are obtainable from the Senior Administrative Medical Officer, Northern Regional Hospital Board, Reay House, 17 Old Edinburgh Road, Inverness, with whom applications should be lodged by December 10, 1973. (1578)

A STATE REGISTERED SENIOR MEDICAL LABORATORY TECHNICIAN with F.I.M.L.T. and experience in bacteriology and interest in biochemistry is required for a new research laboratory for bacterial metabolism at Central Public Health Laboratory, Colindale Avenue, London, N.W.9. N.H.S. salary rates and conditions of service.—Applications to Public Health Laboratory Service Board, 24 Park Crescent, London W1N 4DA. (1580)

MEDICAL RESEARCH COUNCIL LABORATORY OF MOLECULAR BIOLOGY. A vacancy has arisen for a Postdoctoral Organic Chemist or Biochemist in a group working on the partial synthesis and folding properties of proteins. Two-year appointment in the first instance; stipend about £2,100 per annum.—Applications, giving details of age, qualifications and experience and the names of two referees to Dr. R. C. Sheppard, M.R.C. Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, as soon as possible. (1587)

LANCHESTER POLYTECHNIC

Coventry - Rugby

Applications are invited for the following posts:

FACULTY OF ENGINEERING

LECTURER GRADE II IN

Production Engineering

Economics for the Construction Industry

RESEARCH ASSOCIATE/ASSISTANT (2 POSTS) IN

Electrical, Mechanical, Production Control or Civil Engineering, Educational Technology

FACULTY OF APPLIED SCIENCE

PRINCIPAL LECTURER AND LECTURER GRADE II IN

Mathematics

SENIOR LECTURER/LECTURER GRADE II IN

Physics

LECTURER GRADE II IN

Operational Research

RESEARCH ASSOCIATE/ASSISTANT IN

Applied Numerical Analysis

Chemical Metallurgy (Corrosion Fatigue)

Salaries:

Principal Lecturer: £3581 - £3989 - £4499 p.a.

Senior Lecturer: £3291 - £3655 - £3928 p.a.

Lecturer Grade II: £2515 - £3243 p.a.

Research Associate: £1846 - £2008 p.a.

Research Assistant: £1360 - £1522 p.a.

In certain circumstances the commencing salary for the above posts may be above the minimum scale. The qualifications and experience for appointment are stated in Further Particulars, which are available with application forms, from Assistant Secretary (Personnel), Lanchester Polytechnic, Priory Street, Coventry CV1 5FB, (Telephone: 24166 Extension 392) returnable by 30 November 1973. (1576)

North East London Polytechnic

Technician T3—Geology

Applications are invited for the above post in the Department of Chemistry, based at our West Ham Precinct, Romford Road, London E.15. Duties will be in the field of GEOLOGY involving maintenance of collections, servicing the sections laboratory, class preparations and the preparation of samples and slides. Applicants should possess at least ONC/AIST level qualifications with preference given to candidates with experience in the Geology field. Knowledge of photography and general laboratory procedures an advantage. Salary on a scale ranging from £1521 to £1749 per annum inclusive. Please telephone our Staffing Office, 01-555.0811 ext. 31, ref. S/CF123 for an application form and return it by 29 November, 1973. (1622)

MEDICAL RESEARCH COUNCIL

RADIOBIOLOGY UNIT, HARWELL, BERKSHIRE

TECHNICAL ASSISTANT (BIOLOGIST) wanted. Excellent opportunity for (a) Young Graduate or (b) Holders of HNC to join a research group investigating genetic effects of radiation and other agents in small animals. Varied work involving animal genetics, cytogenetics, tissue culture etc. Salary according to age and qualifications. Fringe benefits include modern hostel accommodation for single men and women at a reasonable cost, excellent social facilities and proximity to Oxford.

Applications in writing to: The Administrator, Medical Research Council, Radiobiology Unit, Harwell, Berkshire. Reference MFL/32. (1613)

Graduate Biochemist/ Plant Physiologist

Shell Research Ltd., Sittingbourne, Kent, have a vacancy for a young graduate biochemist or plant physiologist in the Biochemistry and Plant Physiology Division of their Milstead Laboratory of Chemical Enzymology. You will participate in a study of the metabolism of hormones in plants and of the enzymes involved. There will be extensive use of radio isotope techniques. You will be expected to have knowledge of and experience in a variety of biochemical techniques. You should have a good Honours degree and an M.Sc. or Ph.D in Biochemistry or Plant Physiology. Chemistry post-graduates will also be considered if their studies have covered a substantial amount of plant biochemistry and enzymology. The level of appointment will depend on your background and experience; the salary will be competitive. Please write, giving details about your background and experience, to Shell Research Limited, Recruitment Division, PNEI/31, Shell Centre, London SE1 7NA.

(1636)

UNIVERSITY OF TORONTO DEPARTMENT OF PHYSICS

Applications are invited for a faculty position at the level of ASSISTANT PROFESSOR in the Department of Physics. Applicants should have a Ph.D. and research experience in solid earth physics. The solid earth physics group in the Department of Physics has an active and well supported research programme in geomagnetism, crustal seismology, tectonics and geochronology, and works in close co-operation with the Department of Geology. Appointment will be effective July 1, 1974.

Applicants should send curriculum vitae and names of three referees to: Professor D. J. Rowe, Department of Physics, University of Toronto, Toronto M5S 1A7, Ontario, Canada. (1439)

RICHMOND COLLEGE CITY UNIVERSITY OF NEW YORK DIVISION OF PURE AND APPLIED SCIENCES ENVIRONMENTAL SCIENCE

Applications are invited for a faculty position in geology, oceanography, or meteorology. The position involves active participation in the graduate Environmental Science programme and related upper-level undergraduate course offerings. A PhD in an appropriate field is required; rank depends on experience. Salary and benefits are among the highest in the U.S. Richmond College is an upper-division unit of C.U.N.Y. located on residential Staten Island, close to, but detached from, mid-town New York City.

Send résumé and references to Dr A. M. Levine, Division of Pure and Applied Sciences, Richmond College, 130 Stuyvesant Place, Staten Island, New York 10301, USA. (1556)

AGRICULTURAL RESEARCH COUNCIL INSTITUTE FOR RESEARCH ON ANIMAL DISEASES COMPTON, BERKSHIRE HELMINTHOLOGIST

Applications are invited from graduates with at least an upper second class honours degree and a minimum of two years' research experience for a vacant post in the Institute's Department of Parasitology. Preference may be given to a candidate who has obtained a Ph.D. degree. The successful candidate will be required to conduct research on nematodes of farm livestock and initially will be expected to study nematode/bacterial interactions.

The appointment will be in the H.S.O. (£2,076 to £2,667)-S.S.O. (£2,615 to £3,640) scales according to qualifications and experience, plus a 41 per cent allowance to offset F.S.S.U. superannuation contributions. Applications, accompanied by a curriculum vitae and the names and addresses of two referees, should be submitted to the Institute Secretary, citing vacancy No. 153, by November 30, 1973. (1496)

RESEARCH ASSISTANT WANTED

to join a small team working on problems of the relation between enzyme induction, nutrition, and cell injury by environmental chemicals. Biochemistry graduate preferred, but what the post requires most is interest and willingness to learn many techniques ranging from spectrophotometry to making diets. Salary: £1,400-£1,800 (Whitley Council scale).

Applicants write to: Dr A. McLean, Department of Experimental Pathology, UCH Medical School, University Street, London WC1, giving details of any experience and qualifications. (1559)

GRADUATE OR POSTDOCTORAL RESEARCH ASSISTANT

required for one year in the first instance, to work in the Department of Microbiology under the direction of Professor C. A. Mims on the pathogenesis of murine cytomegalovirus infection. Some postgraduate experience in virology and tissue culture desirable.

Initial salary in the range £1,569 to £2,550 according to qualifications and experience.

Applications, together with the names of two referees, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, by December 15. (1593)

UNIVERSITY OF IBADAN NIGERIA

Applications are invited for (a) SENIOR LECTURESHIP or (b) LECTURESHIP IN DEPARTMENT OF VETERINARY MEDICINE AND SURGERY. Applicants should be holders of appropriate qualifications and possess some teaching and research experience. Salary scales: (a) N5,030 to N6,150 per annum; (b) N2,760 to N4,830 per annum (£1 sterling=N1.59). The British Government may supplement salaries in range £750 to £1,150 per annum (sterling) for married appointee of £250 to £650 per annum (sterling) for single appointee (normally free of all tax) and provide children's education allowances; superannuation scheme; biennial overseas leave.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than December 17, 1973, to the Registrar, University of Ibadan, Ibadan, Nigeria. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (1604)

CHELSEA COLLEGE UNIVERSITY OF LONDON

RESEARCH TECHNICIAN (TEMPORARY) GRADE 3 required to work on an Environmental Research Project in the Department of Applied Biology of the Biological Sciences Group. Experience of atomic absorption and spectrophotometry essential. Salary scale £1,825 to £2,095 per annum including London Allowance.

Application forms from Mr K. Harris (N), Department of Applied Biology, Chelsea College, Hortensia Road Annexe, London SW10 0QX. (1605)

UNIVERSITY OF ADELAIDE

Applications are invited for the following appointments:

LECTURER IN BOTANY from beginning of 1974, to teach at both undergraduate and postgraduate levels in ecology. Higher degree required. Field should be relevant to current environmental problems and might include plant ecology, general ecology (provided interests embrace plants) or related topics, such as phytoplankton and marine productivity or physiology of plants under stress. (15.12.73).

TEACHING FELLOW IN ORGANIC CHEMISTRY for 1974 from candidates with Ph.D. degrees; to be responsible for practical courses including course innovations and to undertake research with existing research groups, which enjoy modern facilities of high standard. (7.12.73).

Salary scales: Lecturer SA8,698-SA470 (1)-SA469 (6)-SA11,982; with superannuation on the F.S.S.U. basis; Teaching Fellow SA7,270-SA286 (3)-SA285 (2)-SA8,698; a non-superannuated and non-tenured appointment.

Further particulars about these posts and the conditions of appointment and other information sought will be supplied on request to the Registrar of the University, or to the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications should be sent in duplicate and giving the information listed in the Statement that will be supplied, to the Registrar, the University of Adelaide, North Terrace, Adelaide, South Australia, 5001. (1606)

RESEARCH SPECIALIST or FELLOW required immediately to carry out cellular biophysical research in the Laboratory of Biophysics, Department of Biological Sciences, University of Denver, Denver, Colorado 80210, USA, under the supervision of Professor G. B. David, from whom further particulars may be obtained. Experience in ultrastructural work, enzyme histochemistry or cell isolation techniques required. Bachelor's or Master's degree and adequate post-graduate experience needed. Exceptionally well equipped laboratory available. (1617)

UNIVERSITY OF MANCHESTER

Applications are invited for the post of **LABORATORY SUPERVISOR** in the Department of Physiology. The Department is housed in the new Medical School Building and has well equipped laboratories and workshops. Duties will include the recruitment and supervision of technical staff and the provision of a technical service covering both teaching and research. The successful candidate will also be required to advise the Head of Department on the use and purchase of equipment and apparatus and be responsible for the maintenance of expenditure records. Applicants should have an HNC or equivalent qualification and a minimum of 10 years' relevant experience preferably in a biological sciences background. Salary scale £2,817-£3,201 p.a.

Applications, giving full details of age, qualifications and experience together with the names of two persons to whom reference may be made should be sent as soon as possible to Professor S. Thomas, Department of Physiology, The University, Stopford Building, Manchester M13 9PT, from whom further particulars may be obtained. (1609)

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS. AL5 2JQ

A **SCIENTIFIC OFFICER** is required to work at Broom's Barn Experimental Station on magnesium and other nutrients for arable crops.

The appointment will be for a period not exceeding four years, and there will be an opportunity for a suitably qualified appointee to register for a higher degree.

Qualifications—1st or 2nd class honours degree in appropriate agricultural science subject. Appointment in grade of Scientific Officer (£1,318 to £2,177 per annum) (under review). Starting salary according to age, qualifications and experience.

Applications to the Head of Broom's Barn Experimental Station, Higham, Bury St. Edmunds, by December 7, from whom further particulars may be obtained. (1620)

UNIVERSITY OF TORONTO
DEPARTMENT OF GEOGRAPHY

Applications are invited for a position in physical and biogeography, Department of Geography, St. George Campus, University of Toronto, beginning July 1, 1974. The successful candidate will be expected to develop and teach courses in natural environmental systems in close relationship with existing specialised courses in physical geography and resource management. The courses will be at both the introductory and more advanced levels. The candidate should have a Ph.D. in Geography or another appropriate field. Preference will be given to candidates with a demonstrated interest in ecosystems, both natural and man-modified. The rank will be either **ASSISTANT** or **ASSOCIATE PROFESSOR**.

A letter of application, with curriculum vitae and the names of three referees, should be sent to Professor J. Spelt, Chairman, Department of Geography, University of Toronto, Toronto M5S 1A1, Ontario. Applications should be submitted before February 15, 1974. (1616)

UNIVERSITY OF TORONTO
ASSISTANT PROFESSOR IN
BIOCHEMISTRY

Applications are invited for the position of Assistant Professor in the Department of Biochemistry, to take effect from July 1, 1974, or as soon thereafter as possible. The successful applicant will be required to take part in the teaching duties of the Department and develop his own research programme. The Department is involved in teaching undergraduates in the Faculties of Medicine, Dentistry, Arts and Science, and Nursing, as well as the Graduate School. The minimal salary for the position is \$14,300.

Applicants with suitable qualifications should send a curriculum vitae and the names and addresses of three referees, to Professor T. Hofmann, Department of Biochemistry, University of Toronto, Toronto, Canada M5S 1A8, to reach him not later than January 31, 1974. (1615)

THE MOTOR INDUSTRY RESEARCH
ASSOCIATION
MAN AND VIBRATION

An **ENGINEER/PHYSICIST** is required to join a small research team investigating the effects of road vehicle vibration on man.

Preference will be given to candidates with R&D experience, and in particular those experienced in the use of one or more of the following:

Electronic recording and analysing equipment
Statistical analysis techniques
Digital and analogue computing.

Qualifications: Degree or C.Eng.
The starting salary in the range £1,700-£3,200 will depend on qualifications and experience.

Apply in writing to MTP, Warrington, Cheshire.

CSIRO
AUSTRALIA

DIVISION OF PLANT INDUSTRY, CANBERRA, A.C.T.

RESEARCH SCIENTIST

FIELD:

PLANT/WATER RELATIONS

GENERAL. The Division of Plant Industry of the Commonwealth Scientific and Industrial Research Organization, with headquarters at Canberra, is conducting a comprehensive programme of crop and pasture research based on field and phytotron experiments in a number of disciplines including Agronomy, Nutrition, Physiology, Biochemistry, Genetics, Ecology, and Agricultural Systems. The Crop Adaptation Section is studying the response of a range of crops, including cereals and protein and oil seeds, to dryland conditions.

DUTIES. To conduct field and controlled environment studies on the physiological basis of adaptation to water stress in rain-fed crops.

QUALIFICATIONS. A Ph.D. degree or equivalent qualifications and demonstrable research ability.

SALARY. The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A8,489-\$A12,932 p.a. An outstanding applicant may be offered appointment at a higher level.

TENURE. Either a fixed term or an indefinite appointment may be negotiated. An indefinite appointment carries Australian Government Superannuation benefits.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 130/1248, should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64-78 Kingsway, London, WC2B 6BD.

by the 14th December, 1973.

Applications in U.S.A. and Canada should be sent to:

The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, NW,
Washington, D.C. 20036, U.S.A.

(1582)

Newcastle Regional Hospital Board

REGIONAL MEDICAL PHYSICS
DEPARTMENT

Physicist (basic grade)

Applications are invited for the post of Physicist in the Cardiology Section of the Regional Medical Physics Department, Newcastle General Hospital. This Section is concerned with patient monitoring during surgery and intensive care, computer analysis of catheterisation data and applications of electronics to cardiology. Candidates should have a good honours degree as well as a keen interest in electronics. There may be opportunity for taking a higher degree.

Further information may be obtained from the Chief Physicist of the department (Newcastle 31577).

Salary £1,566 per annum rising by annual increments to £1,842 per annum at end of two years.

Applications to the Secretary, Newcastle Regional Hospital Board, Benfield Road, Walker Gate, Newcastle upon Tyne, NE6 4PY within three weeks.

(1581)

British Museum (Natural History)

Science Writer

The Museum is developing a new exhibition to present a modern view of natural history. A "science writer" is needed to prepare copy and caption material for use in the new exhibition as well as guide books and information leaflets relating to the displays.

The person appointed will also be responsible for writing expositions on recent advances in natural history, for sale to the general public.

All this writing will be done in conjunction with the scientific staff of the Museum.

Candidates should normally have a 1st or 2nd class honours degree in a scientific subject and have a broad knowledge of the biological sciences. They must offer evidence of a facility for presenting complex information in clear and attractive non-technical language without prejudicing its scientific accuracy. A lively interest in communication and modern natural history is required.

Appointment will be as Senior Scientific Officer (£2790-£3815), Higher Scientific Officer (£2251-£2842) or Scientific Officer (£1493-£2352), according to age, qualifications and experience.

For further information and an application form (to be returned by 7 December 1973), write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB or telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service). Please quote SB/11/DK.

(1557)

Senior Toxicology Technician

Smith Kline & French Laboratories Limited is an international leader in the pharmaceutical industry. The Research Institute at Welwyn Garden City is part of the European Research function.

A Senior Toxicology Technician is required to lead the animal studies team in the Toxicology Department which is concerned with the safety assessment of new compounds.

Minimum requirements are

experience with laboratory animals and the possession of a Home Office licence. H.N.C. or F.I.A.T. is preferred. This is a post which is particularly suitable for someone with an ability to organise.

As part of an international organisation the company offers an excellent range of benefits. Salary is negotiable dependent upon experience.

Please write, giving brief details of career to date to:

The Personnel Officer,
Smith Kline & French Laboratories Limited,
Mundells, Welwyn Garden City, Herts.

(1608)

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS. AL5 2JQ

SCIENTIFIC OFFICER required to help head of department with research on physicochemical factors influencing the performance of pesticides, and on methods of improving pesticide use. At present the behaviour of systemic insecticides and fungicides in soil and their uptake by plants are being studied, but the future programme is expected to involve a range of problems including studies on uptake of chemicals by insects.

Minimum qualifications: pass degree, HNC or the equivalent, preferably with chemistry or agricultural chemistry as a main subject. Starting salary £1,318-£1,590 according to qualifications and experience, on scale to £2,177. Superannuation with allowance to offset contributions.

Applications, naming two referees and quoting reference 2042, to the Secretary by December 7, 1973. (1619)

ROWETT RESEARCH INSTITUTE

BUCKSBURN, ABERDEEN, AB2 9SB

SCIENTIFIC OFFICER

Applications are invited for a scientific post in the Department of Experimental Pathology. The successful candidate will be encouraged to undertake original work on toxic effects of dietary constituents in farm animals. A special interest in EM techniques and ultrastructural morphology, and ability to work with farm animals, are essential.

Salary scale is £1,318 per annum rising to £2,177 per annum. Candidates should have at least a good second class honours degree in science, and salary placing will be according to qualifications and post-graduate experience. The post is superannuated with a non-pensionable allowance to offset contributions.

Applications, containing full biographical details and names and addresses of two referees, should reach the Secretary of the Institute before December 14. Further particulars of the duties of the post can be had on application. (1611)

QUEENSLAND INSTITUTE OF TECHNOLOGY

QUOTE: V. 159.73

SENIOR TUTOR IN ORGANIC CHEMISTRY

Applications are invited for the above position within the Department of Chemistry. Preference will be given to candidates who have a higher degree and/or industrial experience. It would be advantageous for applicants to have some experience in food science or applied biochemistry. The successful applicant will carry out demonstrating, tutorial and some lecturing duties and preferably be available before August, 1974.

Salary range: \$6,969-\$7,855 per annum. Further particulars may be obtained from the Registrar.

Applications, including curriculum vitae and the names and addresses of two referees, by December 31, 1973, to: The Registrar, Queensland Institute of Technology, P.O. Box 246, North Quay, Queensland 4000, Australia. (1610)

RESEARCH ASSOCIATESHIP in the Laboratory of Biophysics, Department of Biological Sciences, University of Denver, Denver, Colorado 80210, USA, to carry out research in ultrastructural chemistry under the supervision of Professor G. B. David, from whom further particulars may be obtained. The appointment, available immediately, is for 1 calendar year, renewable. Minimum qualifications include a doctoral degree and appropriate research experience. Exceptionally well equipped laboratories available. (1618)

UNIVERSITY OF EDINBURGH

DEPARTMENT OF GENETICS

POSTDOCTORAL RESEARCH FELLOW

A vacancy exists for a Postdoctoral Research Fellow in a programme concerned with mutation induction in continuous cultures of micro-organisms. Experience in genetical work on micro-organisms required; biochemical experience desirable.

Salary on scale £1,929-£2,388. Applications (in writing), together with curriculum vitae and the names of two referees, should be sent to the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, not later than December 20, 1973. Please quote reference 5081. (1630)

THE ROYAL VETERINARY COLLEGE LONDON

DEPARTMENT OF PATHOLOGY

Applications are invited for the post of VIROLOGIST to assist in a research project on cytomegalovirus infection of pigs, financed by the Agricultural Research Council.

The post will be particularly attractive to those interested in persistent infections by herpes viruses; good facilities and germ-free piglets are available. There would be opportunities to study for a higher degree. A veterinary qualification would be an advantage but is not essential.

Salary in the Lecturer scale, up to £3,045 p.a. Superannuation benefits under FSSU.

Application forms and further details available from the Assistant Secretary (Personnel) (N), The Royal Veterinary College, Royal College Street, London NW1 0TU. (1623)

UNIVERSITY OF WESTERN AUSTRALIA PERTH

Applications are invited for the following appointments from as early as possible in 1974:

ANATOMY

SENIOR LECTURER or LECTURER in Anatomy or Human Biology in the Department of Anatomy. This post could be of interest to a medically qualified person who has experience in the field of gross anatomy teaching and its clinical applications. Alternatively, an individual with training in physical anthropology who can teach gross anatomy to medical and science students would also be suitable. Research support for a major project in the physical anthropology of the Western Australian Aboriginal population is very likely to be available from the Australian Institute of Aboriginal Studies. Further information can be obtained from the Head of the Department, Professor D. B. Allbrook.

MEDICINE

ASSOCIATE PROFESSOR (1 position), SENIOR LECTURER (2 positions), LECTURER (2 positions) and LECTURER (temporary appointment for 1974) in the Department of Medicine. The Department includes teaching beds at each of the following hospitals: Fremantle Hospital, Repatriation General Hospital Hollywood, Royal Perth Hospital and Sir Charles Gairdner Hospital. The present research interests of the Department are gastroenterology, cardiology and renal disease. The appointees will be responsible for inpatient and outpatient care, teaching and research. They may be located at one or other of the University teaching hospitals. Candidates must have a medical qualification, registrable in the State of Western Australia, and the MRACP or an equivalent higher qualification is essential.

The salary ranges are: Associate Professor—\$A15,940 p.a.; Senior Lecturer—\$A12,268-14,308 p.a.; Lecturer—\$A8,698-11,982 p.a. The appointees in Medicine will also be entitled to the following differentials for clinical responsibilities: Associate Professor—\$A3,000 p.a.; Senior Lecturer and Lecturer—\$A2,500 p.a. Permanent conditions of appointment will include superannuation similar to FSSU, fares to Perth for appointee and dependent family, removal allowance, study leave and long service leave and housing loan scheme. A temporary appointee from within Australia will be entitled to fares to Perth for himself and wife, and from elsewhere to appointment expenses up to \$A1,000. Further information is available from the Staffing Officer.

Applications in duplicate, stating full personal particulars, qualifications, experience and earliest date of availability, should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009, by December 15, 1973. Candidates should request three referees to write immediately to the Staffing Officer. (1625)

VICTORIA UNIVERSITY OF WELLINGTON NEW ZEALAND

LECTURESHIP IN MATHEMATICS

Applications are invited for the above-mentioned post in the Department of Mathematics. Applicants should have qualifications in mathematical statistics together with some practical experience in the application of statistics. Within the Department and Applied Mathematics Division research is undertaken in Markov processes, point processes, applications of statistics in geophysics, time series, optimization theory.

Salary range: NZ\$6,575-NZ\$8,343 p.a. Superannuation is available on an FSSU basis and an allowance is made towards travel and removal expenses.

Further particulars of the post, together with conditions of appointment and application procedure available from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Applications close on February 28, 1974. (1629)

Organic Chemists

Roche Products Limited is part of one of the world's leading Pharmaceutical Companies, offering research facilities of the highest standard at new laboratories in Welwyn Garden City, Hertfordshire. A variety of project groups, bringing together various scientific disciplines ensure that there are opportunities at all levels for synthetic organic chemists and technicians wishing to develop their talents and contribute towards the solution of challenging problems. We have openings for:

Scientists

Ph.D. Chemists to undertake creative research and direct the work of small chemical groups in the field of research for medicinal products.

Assistants

H.N.C., G.R.I.C. or first degree Chemists to carry out practical research in various fields.

Technicians

An opportunity for those with at least 'O' level and preferably 'A' level or O.N.C. Chemistry to develop practical skills, working as part of a team with a chance to undertake further study through day release.

All positions carry excellent Conditions of Service and fringe benefits. Further details of the openings available, together with an application form and Company booklet may be obtained from the Senior Welwyn Personnel Officer.

ROCHE

Roche Products Limited
Welwyn Garden City Hertfordshire AL7 3AY

(1553)

National Development Programme in Computer Assisted Learning Programmer-Scientist

Applications are invited for three posts of Development Officers (Computing) at University College London, Chelsea College London and University of Surrey, Guildford, in connection with a joint project on the use of Computers in the Undergraduate Science Curriculum, which is part of the National Development Programme in Computer Assisted Learning. The work involves close co-operation with academic staff in the preparation of computing programs, to be incorporated in teaching packages and in their documentation. Candidates should have graduate level qualifications and substantial programming experience, a background of science would be an advantage. The posts are temporary, in the first instance for two years, within a basic salary range £1,929 to £2,553 depending on age, qualifications and experience.

Further particulars can be obtained from the Project Director, Professor L. Castillejo, Department of Physics and Astronomy, University College London, Gower Street, London WC1E 6BT. (1560)

NATIONAL INSTITUTE OF AGRICULTURAL BOTANY TECHNICAL OFFICER

required in Cereals Section, Systematic Botany Branch. A degree in Botany or Agriculture with appropriate postgraduate experience and a knowledge of cereal varieties required. Salary scale £1,402-£1,925 or £2,087-£3,640, depending on age, qualifications and experience. Further particulars and application form from the Establishments Officer, NIAB, Huntingdon Road, Cambridge, CB3 0LE. (1612)

May & Baker Ltd

Physiologists/Pharmacologists

Applications are invited from graduate pharmacologists or physiologists interested in a career in the development of new therapeutic agents for the following posts:

Post-Doctoral Research Scientist for work with a team engaged in the study and development of new anti-asthmatic agents including prostaglandin-like drugs. Recent developments are most interesting and the work should have great appeal for a good research-orientated scientist interested in seeing a practical outcome to his work.

Post-Doctoral Research Scientist for work on gastric secretion. To develop and extend work of considerable promise already in progress leading to a new agent for the treatment of gastric and duodenal ulcers.

A Research Assistant with a good first degree together with some experience in drug research for work with a team involved in the study of new drugs for the treatment of coronary heart disease and atherosclerosis. Work of considerable interest is already in progress.

The research facilities provided by the May & Baker Research Institute are recognised as excellent. Team work is encouraged, as is publication in scientific journals and attendance at meetings of scientific societies.

May & Baker provide first-class conditions of employment including a highly competitive starting salary and contributory pension scheme with free life assurance cover.

Assistance towards removal expenses may be considered in suitable cases. Please apply in writing with details of qualifications and experience to The Personnel Manager, May & Baker Ltd., Dagenham, Essex RM10 7XS, quoting reference number 292/N/73.

SCIENCE PUBLISHERS

have a vacancy for a

SENIOR EDITORIAL ASSISTANT

to work on the preparation and publication of research journals and monographs. Fields of interest vary over natural and environmental science. Applicants should have a science degree, with mathematics to at least A level, and be interested in publishing. Previous experience is not essential, but will be considered in assessing salary.

Write, giving full details, to Dr J. H. Ashby, Pion Ltd., 207 Brondesbury Park, London NW2 5JN. (1563)

LISTER INSTITUTE OF
PREVENTIVE MEDICINE

A TECHNICIAN with HNC or equivalent qualifications in Biochemistry, and a Junior Technician with 'A' levels in Chemistry and Biology, are required in the Biochemistry Department to assist in investigations on the immunochemistry and biosynthesis of blood group specific glycoproteins.

Applications in writing to Professor W. M. Watkins, Lister Institute, Chelsea Bridge Road, London SW1W 8RH. (1599)

BASIC GRADE BIOCHEMIST

DEPARTMENT OF CLINICAL CHEMISTRY

Applications are invited for the above post. Applicants should have an Honours degree in Biochemistry, Chemistry or one of the biological sciences, or hold Associate or Graduate Membership of the Royal Institute of Chemistry. Whitley Council salary and conditions of service.

Application forms from Personnel Department, Guy's Hospital, London SE1; 01-407 3662, ext. 68. (1552)

WHITTINGTON HOSPITAL

HIGHGATE HILL, LONDON N19 5NF

BASIC GRADE BIOCHEMIST required in the Endocrine Laboratory. Previous experience in Endocrine work is not essential as training will be given.

Apply to the Hospital Personnel Officer giving details of qualifications and experience and the names and addresses of two referees. (1549)

TECHNICIAN and JUNIOR TECHNICIAN required for Chemical Pathology Department to work on development of methods for assay of steroid hormones, lipids etc. Candidates qualified in chemistry, biochemistry or medical laboratory sciences preferred. Salary within scale £1,440-£2,292 plus £126 p.a. L.W. for Technician of £762-£1,396 p.a. plus £126 p.a. L.W. for Junior Technician. Apply The Secretary, St. Mary's Hospital Medical School, Paddington W2 1PG, quoting Ref. TCP 2. (1545)

UNIVERSITY OF LEEDS. Laboratory Technician Grade 6 required in the Department of Physiology. Responsibilities would include the operation of teaching laboratories for medical and science students and the supervision and training of subordinate staff. Assistance with the administration and forward requirements of the department would be expected. Apply by letter, stating age, qualifications and experience, to Mr E. French, Department of Physiology, Medical Multipurpose Building, Mount Preston Street, Leeds 2. (1575)

TWO JUNIOR TECHNICIANS required to assist in research into the role of hormones in the onset of labour. This is an MRC project for three years. Salary on the Whitley scale, depending on age and qualifications. Apply, giving full personal details, to Laboratory Administrator, Nuffield Department of Obstetrics and Gynaecology, John Radcliffe Hospital, Headington, Oxford. (1564)

PRINCIPAL LECTURER/SENIOR LECTURER in Pharmacology required by Liverpool Polytechnic, School of Pharmacy. Applications are invited from graduates in Pharmacy, Pharmacology, or related fields with specialisation in Pharmacology, who have a higher degree together with appropriate academic and research experience. The person appointed to the Principal Lecturer post will have overall responsibility for the development of undergraduate work in Pharmacology and will be expected to promote postgraduate studies and research work. An appointee to the Senior Lecturer post will contribute to undergraduate and postgraduate teaching and will be expected to engage in research. Excellent facilities are available and a new animal house is nearing completion. Salary: Principal Lecturer—£3,581 to £4,499 per annum; Senior Lecturer—£3,291 to £3,928 per annum. Details available from: Staff Office, Department N, Liverpool Polytechnic, Richmond House, 1 Rumford Place, Liverpool L3 9RH.

The National Radiological Protection Board

HARWELL

require a

SCIENTIST

for the

BIOLOGY DEPARTMENT

of the

RESEARCH AND DEVELOPMENT DIVISION

to join the Biophysics Group whose research programme includes a study of the deposition of radioactive aerosols in lung. The work involves both an experimental investigation and the development of a mathematical model for the calculation of aerosol deposition in lung.

The post is at the Board's Headquarters at Harwell. Applicants should have a first or good second class honours degree in a physical or biological science. Appointment will be in the grade of Scientific Officer or Higher Scientific Officer depending upon qualifications and experience. The salary scales appropriate to these grades are:

Scientific Officer	£1,415-£2,330 per annum
Higher Scientific Officer	£2,225-£2,855 per annum

For further information and an application form write or phone:

The Personnel Officer (A42/N7),
National Radiological Protection Board,
Harwell, Didcot, Berks.

Telephone: Rowstock 600 (STD Code 023-583) Extension 33.

(1607)

UNIVERSITY OF ESSEX

Department of Biology

Biology is an important new area of expansion at Essex University. Dr. J. M. Ashworth has been appointed to the first Chair in the Department, and Biological Sciences will be offered as an Honours Degree scheme to undergraduates entering in October 1974. Applications are now invited for the following appointments:

Senior Lecturer/Lecturer

(£4,368-£5,496 or £1,929-£4,548) with particular interests in

Genetics

for appointment from April 1974. Reference PS/49/N.

Two posts of Lecturer

(£1,929-£4,548) in the field of

Cell Biology

for appointment from October 1974. Reference PS/50/N.

Applications (four copies, quoting appropriate reference), should reach the Registrar, University of Essex, Wivenhoe Park, Colchester CO4 3SQ, from whom further particulars are available, by 10th December, 1973.

(1591)

CHEMIST

With Feed Formulation Experience

Zambia K8000+car

We are looking for a Chemist whose experience is supported by a knowledge of nutritional matters in the cereals-based human foods area and a desire to make a management contribution to the company's future. He will join our associate, the National Milling Company, which is engaged in flour and maize milling and the production of a range of stockfeeds. Based in Lusaka and reporting to the Managing Director, he will be responsible for stockfeed formulations; advising on specifications and purposes of a range of domestic foods based on cereals; and for co-ordinating laboratory work and advising on scientific techniques and procedures. He will be a member of the management committee and be expected to contribute to the overall development of the company's business. Considerable customer contact and some travel are involved.

This key position calls for candidates aged 30+ with feed formulation experience, a sound analytical background and a knowledge of human nutritional problems. Experience in commercial management, especially overseas, would be an advantage.

Starting salary, K8000 (about £4,800); a gratuity of 20% of total salary earned during the contract period will be paid on satisfactory completion of the contract. Three-year contract with renewal option. Other benefits include: return economy air passages for the employee and his family; rent-free furnished accommodation or housing subsidy; education allowance and one return air passage annually for each child above primary stage being educated outside Zambia; six weeks' annual leave.

Please write in confidence, quoting reference U.768, to:

D. Drayton, Management Resources Manager, Spillers Limited, Old Change House, 4-6 Cannon Street, London EC4M 6XB.

 **Spillers**

(1596)

UNIVERSITY OF THE WITWATERSRAND JOHANNESBURG, SOUTH AFRICA LECTURER IN MICROBIOLOGY

Applications are invited for the above post in the Department of Botany. A special knowledge in microbial metabolism and/or microbial industrial applications would be an advantage but not essential for the position offered. The two-year degree course, which is in the process of development caters for both pure and applied aspects of microbiology.

Salary will be in the range of R5,520-R7,935 (£3,350-£4,800 approximately), depending on the appointee's qualifications and experience. Benefits include an annual bonus, pension and medical aid facilities, and a housing subsidy (if eligible).

Intending applicants should obtain the information sheet relating to this post from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged not later than December 15, 1973. The information sheet may also be obtained from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1, with whom a copy of the application should be lodged. (1567)

UNIVERSITY OF HULL DEPARTMENT OF PLANT BIOLOGY

A vacancy exists for a RESEARCH TECHNICIAN (Grade 4) to work in the Biochemistry Section of the Department; to undertake culture of micro-organisms and extraction of materials using standard biochemical techniques. There will be some responsibility for preparations of teaching materials and for disciplinary aspects of the Section. Applicants should have 7/9 years relevant experience, together with an HNC or equivalent qualification. Salary on scale £1,848-£2,163.

Applications, quoting the names of two scientific referees, to the Technical Staff Officer, University of Hull, by November 26. (1621)

UNIVERSITY OF NEW SOUTH WALES SCHOOL OF BOTANY LECTURERS

Salary \$A8,698 range \$A11,982 per annum. Commencing salary according to qualifications and experience.

Two vacancies. High academic qualifications in botany or agricultural science required. Appointees will teach in ecology, algology, cryptogamic botany or cytotoxicology and may contribute to an integrated first year biology teaching programme.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on December 7, 1973. (1538)

SOUTHAMPTON UNIVERSITY HOSPITALS PRINCIPAL SCIENTIFIC OFFICER (IMMUNOLOGY)

As part of a Regional Immunology Service being established by the Wessex Regional Hospital Board, a Principal Scientific Officer is required to help establish and run a service for assessing immunological competence in man. Previous experience in molecular and/or cellular immunology is required. There will be some time available for research, and there is opportunity for liaison with research teams.

Salary £3,516-£5,499 (rise pending) with N.H.S. superannuation.

Enquiries to Dr. G. T. Stevenson, Director, Tenovus Research Laboratory (Telephone Southampton 777222 Ext. 3451). Job descriptions from and applications to the Personnel Officer, Southampton University H.M.C., 119 Tremona Road, Southampton SO1 6HU.

Closing date December 1, 1973.

(1638)

AGRICULTURAL RESEARCH COUNCIL

UNIT OF MUSCLE MECHANISMS AND INSECT PHYSIOLOGY, OXFORD

Applications are invited for the posts of BIOCHEMICAL RESEARCH ASSISTANT and TECHNICIAN to assist in the preparation and analysis of contractile proteins. A degree in biochemistry or experience of protein preparation is desirable. The appointment will be on University scales.

Technician Grade 3, £1,539-£1,734 (under review). Graduate Research Assistant £1,491-£2,556.

Applications, accompanied by curriculum vitae and the names and addresses of two referees should be sent to Professor J. W. S. Pringle, Department of Zoology, South Parks Road, Oxford, OX1 3PS, by November 30, 1973.

(1639)

UNIVERSITY OF NEW SOUTH WALES SCHOOL OF CHEMISTRY LECTURER

A Lecturer in Chemistry is required for academic duties primarily concerned with first year chemistry. Opportunity exists to give other specialised lectures and carry out research. High academic qualifications and some tertiary teaching experience in chemistry required.

Salary: \$A8,698 range \$A11,982 per annum. Commencing salary according to qualifications and experience.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on December 14, 1973. (1537)

UNIVERSITY OF NEW SOUTH WALES SCHOOL OF MICROBIOLOGY LECTURER

Salary: \$A8,698 range \$A11,982 per annum. Commencing salary according to qualifications and experience.

PhD or equivalent qualification, together with training and research experience in general field of microbiology, required. Experience in areas of food or industrial microbiology would be relevant.

Details of appointment including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Apts.), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on December 14, 1973. (1536)

LECTURES AND COURSES

UNIVERSITY OF MANCHESTER DIPLOMA IN BACTERIOLOGY

Applications are invited for admission to the Diploma in Bacteriology course to be held in the session 1974/75. The course is designed to give training and experience in aspects of bacteriology and animal virology which are of general importance in the application of the subject to different specialised fields. Applicants must have qualified in medicine, veterinary medicine, or other branches of science, and have had substantial postgraduate practical experience in bacteriology. Medical Research Council awards may be available to suitably qualified British subjects resident in the United Kingdom.

Forms of application may be obtained from the Department of Bacteriology and Virology, University of Manchester, Stopford Building, Oxford Road, Manchester, M13 9PT, and should be returned as soon as possible, and in any case not later than February 1, 1974. (1550)

TOXICOLOGY RESEARCH

The Toxicology area of our Research Department, situated in modern, well-equipped laboratories in Nottingham, continues to expand as more projects reach advanced stages of investigation and new projects are initiated. Two new opportunities have been created for biological scientists to join the team engaged in the safety evaluation of new medical, animal health and crop protection products.

Reproduction Toxicologist

Will assume responsibility for all reproduction and teratological investigations and additionally, will contribute towards technical documents for product registration in the U.K. and overseas. Applications are invited from good honours graduates in a biological science possessing relevant post graduate experience. (Ref: D 101)

Non-Medical Clinical Biochemist

Will assume responsibility for the development of new assay procedures and for research in biochemical pharmacology relevant to the toxicological assessment of new drugs. Applicants should be keen to innovate and, desirably, have experience of clinical biochemistry in hospital or industrial laboratories. (Ref: D 102)

Conditions of employment are attractive, and include good profit sharing and contributory pension schemes. Some help with relocation expenses will be granted where appropriate.

Please write, giving brief details of age, qualifications and experience and quoting the appropriate reference, to:

J. F. Pattison, Employment Manager,
The Boots Company Ltd.,
Nottingham NG2 3AA

(1631)

NATIONAL RESEARCH COUNCIL, CANADA

Postdoctorate Fellowships in Government Laboratories 1974-75

The National Research Council of Canada offers Fellowships for 1974-75 tenable in its laboratories and administers additional Fellowships on behalf of the following Canadian Government Departments and Agencies: Agriculture Canada; Department of Communications—Communications Research Center; Department of Energy, Mines and Resources; Department of the Environment—Atmospheric Environment Service, Environmental Management Service, Canadian Forestry Service, Inland Waters Directorate, Fisheries and Marine Service, Fisheries Research Board of Canada, Marine Sciences Directorate; Health and Welfare Canada—Health Protection Branch; National Museums of Canada—Museum of Natural Sciences; Atomic Energy of Canada Limited.

An applicant should possess a Ph.D. degree from a recognised university, or expect to obtain such a degree before taking up an award. Candidates having equivalent research experience may be considered. Normally an applicant should not have reached his 36th birthday by March 31 of the year in which the Fellowship is to be taken up. Applicants exceeding this age limit should not be more than one year past Ph.D. graduation. There are no restrictions regarding nationality of applicants, but successful candidates must meet all Canadian immigration requirements. The competition closes on January 15, 1974.

Fellowships have an annual value of \$9,000 and are subject to Canadian income tax. A grant is provided towards the cost of travel.

Inquiries should be addressed to the Postdoctorate Fellowships Office, National Research Council of Canada, Ottawa, Canada K1A 0R6.

(1577)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the following vacancies:

RESEARCH FELLOW/SENIOR RESEARCH FELLOW IN ASTRONOMY

APPLIED MATHEMATICS DEPARTMENT

Salary Range: £1,929-£3,543/£3,708-£4,548. Duties to commence January 1, 1974. Closing date for applications November 15, 1973.

Applications, together with the names and addresses of two referees, should be forwarded to The Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars will be available. Please quote 0940.

(1543)

FELLOWSHIPS AND STUDENTSHIPS

THREE POST-DOCTORAL FELLOWSHIPS IN THE EARTH AND PLANETARY SCIENCES

The Lamont-Doherty Geological Observatory of Columbia University invites scientists interested in any field of the earth and planetary sciences to apply for the following Fellowships.

Two Post-Doctoral Fellowships, each awarded for a period of one year (extendable to two years in special instances) beginning in September, 1974, with a stipend of \$12,000 per annum. One Senior Post-Doctoral Fellowship, the stipend and term of the award to be arranged to suit the special requirements of the successful applicant. Completed applications are to be returned by February 15. Announcements will be made March 31.

Application forms may be obtained by writing to the Director, Lamont-Doherty Geological Observatory, Palisades, New York 10964. (1473)

UNIVERSITY OF MANCHESTER

DEPARTMENT OF ANAESTHETICS

RESEARCH STUDENTSHIP IN APPLIED BIOCHEMICAL RESEARCH

Applications are invited for this post, available now. Candidates should hold a good honours degree in chemistry, biochemistry or pharmacology, and have an interest in the application of gas chromatography and mass spectrometry to biological research, with particular reference to drug metabolism. The successful candidate will follow a research course leading to a higher degree, and will have an opportunity to work on the development of new techniques for the sensitive analysis of narcotic analgesics and other drugs, and their metabolites. Salary according to SRC studentship grade.

Applications as soon as possible to Professor J. Parkhouse, Department of Anaesthetics, University Hospital of South Manchester, Manchester M20 8LR. (1533)

UNIVERSITY OF MANCHESTER

TURNER AND NEWALL RESEARCH FELLOWSHIP

Applications invited for one Fellowship, founded by Turner and Newall Limited, available for post-doctoral research in Chemistry, Physics, Geology, Mineralogy, Metallurgy, Applied Mathematics, Engineering, Medicine and allied subjects. Tenable from October 1, 1974, for two years. Salary range: £1,560 to £1,768 per annum. F.S.S.U.

Particulars and application forms (returnable by February 5, 1974) from the Registrar, The University, Manchester M13 9PL. Quote ref.: 204/73/N. (1535)

UNIVERSITY OF SYDNEY

POSTDOCTORAL FELLOWSHIP IN BIOPHYSICAL CHEMISTRY

Applications are invited for a fellowship to study experimentally either protein-lipid interactions in myelin, or effects of electric fields on conformation of proteins. Salary \$A7,842 a year and travel allowance.

Applications including an account of education and research experience, with names of two referees, should be sent to Prof W. J. Moore, Dept. Physical Chemistry, University of Sydney, Sydney, NSW 2006. (1594)

UNIVERSITY OF LONDON
KING'S COLLEGE
ESMEE FAIRBAIRN
POST DOCTORAL RESEARCH
FELLOWSHIP

Applications are invited for one Esmee Fairbairn POST-DOCTORAL RESEARCH FELLOWSHIP in any aspect of environmental studies which can be investigated adequately at King's College Field Station, Rogate, Nr. Petersfield, Hants. The person appointed will be attached to appropriate College departments and will be expected to contribute to teaching programmes at the Station.

The Fellowship is tenable for one year initially from January 1, 1974, at a salary on the scale £1,764 to £1,923. FSSU benefits are payable.

Applications, comprising a curriculum vitae, a detailed scheme of the proposed investigation and the names of two referees, should be sent to the Registrar (N), King's College, Strand, London WC2R 2LS, by November 30, 1973. Details of living accommodation and field facilities at Rogate are obtainable from the Warden (Tel. Rogate 367), with whom arrangement for visiting the station may be made.

(1632)

LECTURES AND COURSES

UNIVERSITY OF SURREY
POSTGRADUATE MEDICAL SUBCOMMITTEE
OF SENATE

M.Sc. IN MEDICAL SCIENCES

The next entry to the M.Sc. in Medical Sciences will be in January, 1974. The course lasts for 2 years all day Wednesdays during the academic terms. The syllabus covers the material for the basic sciences of the primary courses in medicine, surgery, obstetrics and gynaecology, and anaesthetics, but does not exempt students from the relevant primary examinations of the Royal Colleges.

Further details or enquiries may be addressed to the Course Organiser, Dr. H. Hillman, Department of Biological Sciences, University of Surrey, Guildford, Surrey. Telephone, Guildford 71281, extension 573.

(1532)

UNIVERSITY OF LONDON: A course of three lectures entitled 'Genetic Analysis of Control Systems' will be delivered by Professor B. Müller-Hill (Cologne) at 5.30 p.m. on November 26, 27 and 28 at University College (Botany Lecture Theatre), Gower Street, W.C.1. Admission free, without ticket.—Academic Registrar.

Research Fellowships at Continental Universities

Applications are invited for awards by the CIBA-GEIGY Fellowship Trust for the academic year 1974-75.

Two classes of award will be made as follows:—

CIBA-GEIGY Fellowships

CIBA-GEIGY Fellowships are offered to graduates of universities of the United Kingdom and the Republic of Ireland for research into chemistry, biochemistry, chemical technology including chemical engineering, and biology, particularly in its relation to chemistry, at an agreed university including a technological university on the continent of Europe.

Qualifications recent first degree university graduates who intend to undergo training in research for a doctorate or other higher degree at an agreed European university including a European technological university.

Duration of the award the minimum required by the university regulations subject to satisfactory progress, with the possibility of an extension for an additional year.

Scale of awards £1,650 per annum (£1,950 per annum if married) plus travelling expenses.

The candidate should not be in receipt of any other award.

Senior CIBA-GEIGY Fellowships

Senior CIBA-GEIGY Fellowships are offered to lecturers, senior lecturers, readers or those holding comparable positions at United Kingdom or Republic of Ireland universities who are also graduates of these universities and wish to undertake special study at an agreed continental European university including a European technological university.

Duration of the award minimum period of six months and up to two years.

Scale of awards £4,500 per annum plus travelling expenses.

Further details and application forms, which should be submitted before 31 January 1974, can be obtained from The Secretary, The CIBA-GEIGY Fellowship Trust, 30 Buckingham Gate, London SW1E 6 LH.

Cytochalasin A, B and E: Versatile New Tools for Cytological Research, Exclusively from Aldrich.

Cytochalasin (Greek **CYTOS**, cell; **CHALASIS**, relaxation)

Since their discovery in 1964 in the laboratories of the Pharmaceuticals Division of Imperial Chemical Industries Limited, the CYTOCHALASINS (Greek *cytos*, cell-*chalis*, relaxation) have become increasingly important as research probes in cytology. These CYTOCHALASINS, a group of structurally related fungal metabolites (CYTOCHALASINS A and B from *Helminthosporium dematioides*, CYTOCHALASIN E from *Rosellinia necatrix*), share a number of unusual, interesting and characteristic biological effects, though varying greatly in potency in certain aspects. To date, CYTOCHALASIN B has been used in the vast majority of reported experiments.

Major biological effects observed with the CYTOCHALASINS include:

1. *Inhibition of the division of cytoplasm.* Total inhibition of cytoplasmic cleavage is obtained without interference with division of the nucleus resulting in binucleate cells. If cultured cells are allowed to remain in the active medium, nuclear division continues and large multinucleate cells are observed.

2. *Reversible inhibition of cell movement.* When moving L cells on a glass surface are treated with CYTOCHALASIN B,

peripheral and internal cell movements disappear, but are readily restored by washing the cells with normal medium. This effect is best observed by time-lapse cinematographic studies.

3. *Induction of nuclear extrusion.* In this very interesting phenomenon, it is remarkable that a cell can be induced to entirely eject its nucleus within minutes of treatment with a chemical compound. Most noteworthy is the fact that CYTOCHALASIN E rarely produces nuclear extrusion. However, it is unique in producing a "halo" around the nucleus.

The CYTOCHALASINS also exert inhibitory effects on the following biological processes: phagocytosis; platelet aggregation and clot retraction; glucose transport; thyroid secretion and release of growth hormone.

Continued research on these interesting compounds will undoubtedly uncover new effects and help elucidate their hitherto unknown mechanism of action. Space does not allow us to cite well over one hundred references from the literature, but a data sheet and comprehensive bibliography are available upon request. The CYTOCHALASINS are made in England by Imperial Chemical Industries Limited and distributed by the Aldrich Chemical Company.

Maritime Studies and Management

Editor: Professor A. D. Couper, *University of Wales Institute of Science and Technology.*

Assistant Editors: C. H. Cotter, P. H. Fricke, W. E. Scobie, *University of Wales Institute of Science and Technology.*

There is an increasing amount of maritime research being undertaken by economists, geographers, lawyers, social scientists and maritime studies specialists within universities and colleges, and by managers and planners in industry, government and international agencies. Many of the results are inaccessible other than through specialist publications relating to particular disciplines. This new journal will bring together papers concerned with the maritime world which will be of interest and value to teachers, research workers and managers.

Frequency: Quarterly.

Subscription:

Libraries £8.00 per annum.

Additional: £6.00 per annum.

Private: £6.00 per annum.

the **Searle** products for research autumn bulletin

MOUSE ANTI THETA SERUM

It is generally accepted that all cells with the theta alloantigen are thymus-derived and the use of cytotoxic theta antisera to identify thymus-derived lymphocytes has been widely reported. The two specificities of theta antisera are available from Searle, anti theta-C3H and anti theta-AKR.

MICROCOCCLUS DNA-DEPENDENT RNA POLYMERASE

This highly purified enzyme is invaluable for basic studies on RNA synthesis, and has recently been used for synthesising anti-mRNA strands, for analysing template properties of mammalian chromatin and for transcribing the 'sense' strand of ribosomal DNA cistrons with high fidelity.

RABBIT GLOBIN m RNA

Rapid developments in the purification of messenger RNA enable us to offer a highly purified preparation of 9S globin messenger from rabbit reticulocytes. This material will be suitable for studies on translation in a variety of cell free systems.

POLY (dT) CELLULOSE

Recently, it has been shown that most messenger RNA's contain long regions of polyadenylate. These regions will bind the messenger molecules to poly(dT) cellulose, thus effectively isolating them from ribosomal RNA.

Other Products

Purified Encephalomyocarditis virus—
in milligramme quantities.
Six HL-A tissue typing antisera
Cultured Human Lymphocyte cell lines—
in kilogramme quantities.

Bernard Lovell

In *The Story of Jodrell Bank* Sir Bernard described the construction of the telescope and the associated political and financial problems. His new book considers some of the remarkable discoveries in astronomy and space with which Jodrell Bank has been associated since 1957, including the discovery of radio galaxies, quasars, and pulsars. £5.50

Introduction to Stellar Atmospheres and Interiors

Eva Novotny

This textbook in astrophysics is suitable for undergraduate and graduate courses. It reviews the observational data with which the theoretical results must be compared, develops the basic theoretical concepts pertinent to stellar atmospheres and interiors, and gives detailed examples of the calculation of a model solar atmosphere and a number of model interiors.

£8.75 OUP New York

Oceanography

Contemporary Readings in Ocean Sciences

Edited by R. Gordon Pirie

This book of readings is designed for first- and second-year undergraduates in ocean sciences. Its greatest use will be as a supplementary reader with existing introductory textbooks of oceanography. Illustrated £5.25 paper covers £2.70

OUP New York

Challenging Biological Problems

Directions toward their Solution

Edited by John A. Behnke

Seventeen crucial biological problems and ways of solving them are explored in this book of perceptive speculations. Among the subjects covered are genetic intervention, abnormal growth, aging, the biology of aggression, population, and the coexistence of species. £5 OUP New York

Radiation Protection

A Guide for Scientists and Physicians

Jacob Shapiro

This manual on the safe use of radiation sources, including radionuclides, X-ray machines, X-ray diffraction machines, and accelerators provides the information needed by the user to protect himself and others, and to understand and comply with regulations regarding radiation use. £7.50 paper covers £3.50

Harvard

Oxford

Two further volumes in the highly successful Fundamentals of Botany Series

edited by W. A. Jensen
and L. G. Kavaljian

Evolution and Plants of the Past

Harlan P. Banks

This book is a wide-ranging discussion of a number of important aspects of palaeobotany. The basic approach is an examination of the way in which plants have developed from the earliest times. In contrast with the more traditional approach, in which each group of plants is examined separately, this book looks at each geological period and treats its fossil flora as a whole. As a result a much more dynamic and interesting story is told.

£1.60

Plants, Man and the Ecosystem

Second Edition

W. D. Billings

This elementary introduction to ecology discusses the relationship of plant individuals and populations to their environments and to their roles in the ecosystem. The second edition has been completely reset in an attractive new format, and the text has been revised and expanded so that it now includes a discussion of man and his relations with the plant world.

A Broader Debate on Energy

WITH the sudden attention that energy and its wise use is receiving world-wide, it was appropriate that the Royal Society should have convened a meeting to discuss 'Energy in the 1980s' last week. By an amusing coincidence, it started on the day the advertising signs were extinguished in Piccadilly Circus. There was more to our interest in the meeting, however, than simply the (fulfilled) expectation of adding to our knowledge in the field. If scientists and technologists are to speak to the public beyond their own community in a manner that will stimulate discussion and understanding, form is every bit as important as content, so we were particularly interested in the shape that the meeting would take. Two weeks ago *Nature* reported unfavourably on an energy meeting convened by the Royal Society of Canada (246, 56; 1973) largely on the grounds of its conventional format; could this one produce something new?

That it did not was no discredit to Sir Peter Kent who had assembled a distinguished list of speakers. Relevance, however, increases greatly with the proximity of the threat, and since the meeting had been announced, the question had changed dramatically from being what will we have in the 1980s to what will we make do with in 1974. One by one specialists discussed dispassionately their particular interests and supplied a multitude of data but the projections into the 1980s were cautious and assumed a relatively undisturbed society and no surprises, pleasant or otherwise. What was needed to complement these strands was a shuttle to weave cross threads and put the story together according to different patterns. What happens to the projections when oil supplies are cut by 10% in 1973? If the nuclear programme falters how are the other resources strained? If several as yet underdeveloped countries with large populations suddenly acquired an appetite for energy how would projections be affected? (We are, after all, at present seeing the consequences in the world food situation of the growing appetites of developing countries for protein.) And perhaps the key question—is energy saving, either voluntary or compulsory, going to make any impact on energy needs? It may be that what meetings of this sort need is the stimulus of a longish paper which has been read by everyone previously and which is sufficiently provocative that experts can spend their time dismembering and rebuilding rather than pursuing independent paths. Certainly some sort of interlocutor would be a useful addition.

As it happened, the lack of a feel for total situations at the meeting was balanced by the simultaneous launching (surely no accident) of a document by the Friends of the Earth. This booklet, 'World Energy Strategies' by Amory Lovins, is worth reading if only because the author does attempt a synthesis. He works from the hypothesis that a "resource inventory would by itself be useless . . . energy constraints are not mainly dictated by physical scarcity, but are geopolitical, environmental and socio-technical".

Mr Lovins sees coal as the short and medium term solution to the energy problem. On the way to this con-

on the need for constraint in energy usage, particularly in the United States, some caustic words on the safety risks of nuclear fission and some hopeful thoughts on coal. He concludes that "the problems of coal are substantial but can be solved" whereas "governments should suspend their nuclear programmes until enough infallible people can be found to operate them for the next few hundred thousand years". This is an outspoken and biased point of view. Mr Lovins is prepared to give coal the benefit of every doubt, nuclear energy the benefit of none. Nuclear energy has to be judged not only by technical standards but by ethical considerations, whereas coal, the pursuit of which mars thousands annually but which lacks the magical ability to afflict unborn generations, is let off the social hook with a naïve reference to a recently opened Illinois deep mine which "is said to use every kind of safety and health precaution yet still is profitable." We are not the first to point Mr Lovins to Otto Frisch's delightful essay 'On the feasibility of coal-driven power stations'.

Nonetheless, Mr Lovins is a great asset and should not be lightly dismissed. For too long, discussion of broad multidisciplinary issues in the United Kingdom has been subordinated to the pursuit of excellence in individual fields. Decision making has been regarded as so much a province of government that national discussions of policy issues have been sadly lacking. For all that we may disagree with the Mr Lovinses, we need them in order to open up the debate. Preferably we need them on the same platforms as the experts and certainly we need them to make a nuisance of themselves.

100 Years Ago

A HEALTHY HOUSE

What a House should be, versus Death in the House. By William Bardwell, Architect and Sanitary Engineer. (London: Dean and Son.)

It would be interesting to have had some references given to sanction our author in claiming the authority of the Duke of Wellington, together with that of Aaron and the High Priests, his successors, for the practice of placing their beds nearly north and south so as to be in the line of the magnetic current. The theory no doubt has its advocates, but can hardly be of universal application, as there are many sound sleepers at all degrees of orientation.

NEWS

More Uranium Found in Britain

THE Institute of Geological Studies reported this week that uranium is to be found in North Wales, the Southern Pennines, the South Wales coalfield, the Midlands as well as in the north of Scotland and south west England. (*Uranium Mineralisation*. . . , S. H. U. Bowie, D. Ostle and C. B. Campbell, IMM Applied Earth Science Transactions Section B, November 1973.)

Deposits in Scotland and in south west England have been previously reported by the IGS. A few thousand tons of uranium in the oxide form, U_3O_8 are to be found in Caithness and Orkney and a few hundreds of tons in the south west of England.

The extent of the deposits now found in Wales and other parts of England are not revealed but the strength, in terms of parts per million of uranium ore, makes it clear that the deposits are at present not of economic significance. But they represent reserves, which if they turn out to be of sufficient tonnage, might well prove to be of strategic importance. The possibility of mining these deposits will not arise until the high quality ore at present being mined in Canada and South Africa are worked out and the cost of ore inexorably rises.

The deposits in the Orkneys are low grade and widespread but Dr Bowie and colleagues report that in places the content of uranium in phosphatic rock is as high as 1,000 parts per million, amounting to 0.1% enrichment, which compares favourably with the quality of uranium ore now being mined in other parts of the world. But the uranium content of the dark shales in the Orkneys rarely exceeds 200 parts per million. In the south west of England, however, the ore is found in high grade concentrations but of low tonnage. The new survey revealed, however, several new sources of uranium but they are also of modest tonnage or low grades. At Fingle Bridge, a rich zone has been found of 0.5% enrichment which is over 5 feet wide.

At Luton on the western side of Dartmoor a vein has been found which is one foot wide, and a sample analysis showed that the uranium content was of the order of 3%. This same vein contains also copper, lead, silver and arsenic.

Several other sources of uranium have been found in the south west of England but the full extent of some of the deposits can not be revealed unless drilling takes place.

The present survey was restricted to sampling of stream water, sediment, wells and boreholes. When the terrain was suitable the countryside was scanned for evidence of radioactivity by carrying scintillation counters in vehicles and in some place by scanning for radioactivity on foot.

Of the newly reported finds of uranium, the IGS team reports that although some uranium is to be found in North Wales, it is not of economic grade. "The rocks represent a major crystal enrichment but no evidence has yet been found of uranium concentrations sufficient to produce deposits of potential value."

The uranium concentrations in the southern Pennines are very low (10-30 parts per million) but in the South Wales coalfield, concentrations of 270 ppm have been found. It is unlikely, however, that the element is present here in sufficient quantities to be of economic significance, according to Dr Bowie and colleagues. The highest concentration

of uranium found in the Midlands amounted to 162 ppm and this is in a shallow peat deposit.

No marked radioactivity was found in extensive examinations across the Midlands, from the Welsh borderland in Montgomeryshire and Radnorshire to Lincolnshire and Nottinghamshire except for some activity near the known outcrop of Cambrian shale near Nuneaton.

Uranium has never been mined on a large scale in Britain although it was obtained as a by product of a pitch blend mine near St Austell earlier this century. Britain, however, is not likely ever to produce enough uranium to fulfill its needs. The nuclear reactors at present in operation in Britain need more than a thousand tons of uranium a year to keep them in production. When it does become economic to think of mining uranium in Britain then the reported reserves (a few thousand tons of U_3O_8) represent at the present rate of usage, a few years' supply.

STEEL

European Opportunities

An improved coordination of steel research within Europe was called for by Dr Robert S. Barnes, director of research and development at the British Steel Corporation, last week. Dr Barnes, delivering the annual Hatfield memorial lecture, said that "the need to exchange technical views, to criticise, construct and develop cooperatively concepts for joint European research activity is now more necessary than ever it was".

Dr Barnes was critical of the arrangements existing at present within Europe for collaborative research in steel. The task of processing and assessing the waves of uncoordinated and untranslated proposals which sweep through the EEC and its advisory committees several times a year is too great, according to Dr Barnes. "The commission's advisory committees—there must be about a hundred of these—only deal with narrow technical areas and are often more concerned with technical details rather than with the broad needs for the individual research projects or with the eventual application of their outcome."

There is therefore a need for efforts to be concentrated on a few clearly defined and large projects, which for one

thing would ease the communication and administrative problems of steel research in Europe, said Dr Barnes.

In order to achieve these objectives, the European Commission will have to be advised in a different way. At present the commission's advisory experts are appointed as individuals and it would be advantageous if these experts represented the collective view of the European steel industry. Dr Barnes called for the industry to set up just such an organisation which would "produce and regularly update a strategy for collaborative research". It is possible that l'Association Européenne pour la Promotion de la Recherche Technique en Siderurgie could fill this role.

Dr Barnes also highlighted in his lecture a possible way of making steel in the future by using the gas emitted from a High Temperature Nuclear Reactor as a reducing agent. The gas would first be used to convert the iron ore to a pre-reduced iron. This would then be fed to an electric arc powered by electricity obtained from the waste heat of the first process.

Such direct use of nuclear power could be the way in which most steel will be made in the twenty-first century. It could, however, be introduced even sooner if the costs of using other forms of energy, such as coal or electricity, escalate faster than anticipated.

NUCLEAR REACTORS

Britain's Power Dilemma

THE miners, Arabs and power workers between them made life so bad for Britain's power industries last week that a meeting of the Nuclear Power Advisory Board, which was to take another step along the troubled road to choosing Britain's next reactor type, had to be cancelled. Everyone had too much on their plates already.

An announcement is expected early next year from Mr Peter Walker, Secretary of State for Trade and Industry, on which type of reactor Britain is to build next.

The Nuclear Power Advisory Board has already had presentations from the chief parties interested in the choice and has learnt from the Central Electricity Generating Board that it wants to buy light water reactors from the United States—preferably Pressurized Water Reactors (PWRs) from Westinghouse.

The board argues that the light water reactors are cheaper and more proven than anything else available. The alternatives are fourfold. Britain could build more Advanced Gas Cooled Reactors. Five of these are being built. All of them are late, and the first is not due to produce full power until 1975.

Two of the other possibilities require development. These are the Steam Generating Heavy Water Reactor, a 100 MW prototype of which has been performing well at Winfrith in Dorset since 1967, and the High Temperature Reactor. But the board argues that it is too late to build SGHWR. It offers too little export or development potential, is more expensive than the PWR, a development programme would be required with all its attendant risks and substantial qualities of heavy water would be needed. The High Temperature Reactor also suffers from the need for a development programme. A 30 MW prototype has been operating since 1963, but 30 MW is a far cry from the 1,200 MW size that interests the CEBG. The board is relatively enthusiastic about the design, however, and would like to see a commercial plant built. But it does not want to use the HTR for the large scale programme it is envisaging—six to eight stations on order by 1980. It would rather see the design developed more slowly.

The final possibility is that another Magnox station could be built. In spite of corrosion problems, Magnox stations have performed well and last year produced some of the cheapest electricity. With some redesign work to remove corrosion problems more Magnox stations could be a reliable bet. But the board believes the cost to be prohibitive, perhaps £600 million a station as against about £400 million for a more modern design.

The argument is not quite as simple as the CEBG would have everyone believe. For a start it is unfortunate, to say the least, that the empty order books of the nuclear industry, the government's commitment to reach a decision soon and the CEBG's belief that it will need more nuclear stations by the end of the decade have all combined to force a decision now rather than in eighteen months or two years time, when it will be seen whether at least one of the Advanced Gas Cooled Reactors, costing between them rather more than £1,000 million, works. Equally the CEBG's calculations studiously ignore the question of foreign exchange. With a trade gap running at £289 million in a single month, the government cannot be eager to spend more money abroad than it has to. And a first PWR would be bought lock and stock, if not barrel, from the United States. As the CEBG sees it, Britain's GEC-dominated National Nuclear Corporation would provide the emergency core cooling system, the containment and the chemical engineering of the new station, but the remainder of the nuclear steam supply system would come from abroad.

And the question of safety remains to be answered. The United States Atomic Energy Commission has spent the past two years arguing in public and private about the effectiveness of the Emergency Core Cooling System (ECCS) that is a key part of the PWRs' defence system against a bad nuclear accident. Theoretically the ECCS douses the reactor core in water within seconds of, for example, a broken pipe or blocked pump cutting off the normal cooling water supply to the core. Without water, a dry core heats to 1,800° C within a minute, at which point the fuel and zirconium fuel cans being to melt. An hour after the loss of cooling water the core has flowed to the bottom of the reactor vessel accompanied by steam explosions which, combined with gas pressure, could split the reactor vessel, releasing fission products. A few hours after that, the molten core would have eaten through the reactor vessel and the concrete foundations.

The ECCS is designed to prevent this happening. But no practical test of the system has been made, and an AEC facility known as the Loss of Fluid Test Facility will not be ready to run the crucial experiments on what does actually happen to a dry core until 1975. Theoretical calculations suggested that the emergency core cooling system would prevent these events. But other sums produced different answers, and a small scale test on a simulated reactor core suggested that in the event of 30 to 100% of the cooling water leaving the reactor, only 10% of the emergency cooling water would reach the core. The Loss of Fluid Test should confirm

or quell these doubts. But the answers will not be available by January when Mr Walker has to make his decision.

The CEBG is of course aware of these problems. It has looked at the calculations at its nuclear laboratories at Cheltenham and concluded that the light water reactors are safe enough. But its conclusion is not going unchallenged. The Friends of the Earth have just launched a campaign on energy and its conservation. Their sister organisation in the United States has been at the forefront of the campaign against light water reactors. Last week a spokesman for the British end of the organisation said that "it is a little difficult to explain" how the CEBG has managed to satisfy itself about the safety of light water reactors while the Atomic Energy Commission is still sorting out the problem.

Aside from the safety matter, it is not at all certain that building PWRs will be as easy as the board maintains. Its interest lies in 2,400 MW stations consisting of two 1,200 MW sets. The largest PWR built and operating to date is 1,050 MW. And in spite of talk about buying proven designs, no reactor comes off the shelf. British industry will have to learn to build PWRs just as it has had to learn to build AGRs or would have to learn to build commercial HTRs or SGHWRs. Walt Patterson, a nuclear physicist who works with Friends of the Earth, says "the whole AGR fiasco is entirely conceivable as a re-run with light water reactors". Additionally the complaint is common within the industry and the United Kingdom Atomic Energy Authority that the CEBG cannot resist fiddling with power station designs.

A final question worth asking is why the government, the Atomic Energy Authority, the generating boards and the industry have the current problem to solve at all.

The CEBG seems happy to consign the AGR to oblivion. Yet it is the

Forthcoming Natures

NEXT week, *Nature* will contain a thirty-two page supplement reviewing science in Australasia.

Nature for Friday, December 14, will be a Christmas issue. In addition to the regular features there will be several pages of specially commissioned articles, chess problems and a quiz.

The two Friday issues of December 21 and 28 will be combined in one large edition that will be published December 21. *Nature Physical Science* and *Nature New Biology* will likewise be published in double issues on December 17 and December 19 respectively.

board that ordered the reactor in the first place, commissioned three separate designs and agreed to build these before a full prototype was constructed. (The Windscale AGR, well though it has run, is a far simpler machine than the commercial stations, built more for fuel testing than as a proper prototype.) The stations were all approved without detailed design work being undertaken.

It is a similar mess that everyone is trying to avoid this time. The choice is not an easy one. As Sir John Hill, Chairman of the Atomic Energy Authority, said at the Royal Society symposium on energy last week "all reactor systems have some problems". He also pointed out that "every time there is a major change of design there will be difficulties". It is possible that light water reactors will prove the final choice. But the CEBG should admit that the case is not as clear cut as it claims.

AUTOMOBILE POLLUTION

GM Breaks Ranks

by our Washington Correspondent
MOTOR manufacturers have recently failed in a last ditch attempt to keep exhaust catalysts off cars sold next year. For months, executives from the car industry have been badgering Congressmen and Senators, trying to win yet another delay in implementing the stringent exhaust emission controls specified by the Clean Air Act, and the matter finally came to a head early this month when the Senate Public Works Committee held a couple of days of hearings on automobile pollution. Spokesmen for the industry warmed over a number of old arguments, seized upon all kinds of real or imaginary fears, and invoked threats of economic and social disaster if the Clean Air Act is not soon modified. But the chief outcome seems to be a huge split in their own ranks.

They were arguing, essentially, for emission controls to be frozen at their present levels for the next two years, and for some rather more stringent controls to be imposed in 1977. Such a delay would put off the need to fit exhaust catalysts, since the present regulations can be met with engine modifications, and the clear intention is to use the breathing space to work to put off that fateful day entirely.

That, at least, is the position taken by representatives of Ford and Chrysler, who were unstinting in their criticisms of the catalyst. But witnesses from the other member of the big three, General Motors, broke ranks and came out with some extraordinary statements in support of the device. But they, too, want the controls relaxed, although only by a small amount.

strator of the Environmental Protection Agency, said that he is not prepared to recommend relaxing or delaying the standards, and the committee shows no sign of taking the initiative itself. Thus, as John J. Riccardo, president of Chrysler put it, since "action must be taken now, or it will be too late", exhaust catalysts will be fitted to cars sold next year.

It was a last ditch attempt by Ford and Chrysler because the Environmental Protection Agency has already given them the maximum amount of time available to meet the standards, and the only possible way to delay things further would be for Congress to modify the Clean Air Act. The act requires that 1975 model cars emit 90% less carbon monoxide and oxides of nitrogen than 1970 models, and that 1976 models emit 90% less oxides of nitrogen than 1971 models. Earlier this year, however, the motor manufacturers persuaded the Environmental Protection Agency to give them an extra year to meet the standards. But part of the EPA's bargain included a provision which requires that all 1975 model cars sold in California must meet strict emission controls—and that will need the use of exhaust catalysts on those cars. The rationale was to force catalysts to be introduced in California next year—1975 model cars will be unveiled in the Autumn of 1974—and nationwide a year later.

Ford and Chrysler executives argued, as they have done for the past two years, that the catalyst is inherently bad technology, and that they would like to use better devices, such as the stratified charge engine, if only they had the time to do it. But, if they are forced to clean up car emissions immediately, they have no alternative to sinking their money into exhaust catalysts at the expense of developing the other technologies.

Six months ago, that was also the complaint put out by General Motors, but at the hearings earlier this month, Edward N. Cole, the company's president, said bluntly that there is no need to modify the interim regulations set for California in 1975, and that the conventional engine equipped with catalytic converters will be the best method of cleaning up automobile pollution. Cole also said that GM cars will be able to meet the 1975 interim standards, and that catalysts will be fitted not only to cars sold in California, but to others as well.

The effect of the split in Detroit's previously united front had the effect of undermining many of the arguments put up for delaying the standards, and environmentalist witnesses at the hearings had little difficulty in playing off one statement from the car manu-

perhaps worth noting, in any case, that only a few months ago, when spokesmen for all three manufacturers were arguing for a year's delay in the 1975 standards, that they all painted pictures of economic disruption and wholesale closures if they were forced to introduce catalysts on all their cars next year. Now, however, not only is General Motors planning to introduce catalysts nationwide next year, but Ford is also planning to fit them to all their California cars and 65% of their others. Environmentalists have been quick to ask what happened to the dire forecasts.

As for the latest round in the battle, the arguments for delaying the standards have revolved around three chief questions—are the standards stricter than necessary simply to protect public health? Will the catalysts lead to another serious health problem, namely, the production of sulphuric acid from sulphur in petrol? And, finally, will they contribute to the energy crisis by decreasing engine efficiency? In each case, Ford and Chrysler argued that it would be sensible to delay implementing the standards until those questions have been answered. Clearly, if catalysts are installed next year and it subsequently turns out that they are not needed, several hundred million dollars will have been wasted.

The question of the standards being stricter than necessary is one on which the manufacturers are almost united, and they have also received direct and indirect support from the National Academy of Sciences for their arguments. In September, for example, Dr Arthur Stern, chairman of an NAS committee which has been looking into auto pollution, said that he believes the standards are three times stricter than necessary. That statement has, of course, been seized by the manufacturers and bandied about in committee rooms and Congressmen's offices ever since, but they are looking to the academy to provide even more support for their case next year. The academy has been given a contract by the Senate Public Works Committee to conduct a massive study of the health effects of pollutants, and the car manufacturers are convinced that when it reports next year, the academy will vindicate their own findings that the standards are much too strict.

In any case, the manufacturers have been arguing with some conviction that the 1975 interim standards should be delayed until the academy has produced its report, since, by next summer, catalysts will already be clamped to car exhausts and it will be too late to turn back if the study finds that they are not in fact needed. But the EPA, in the person of Mr Train, testified that relaxation of automobile controls next year would not only be a waste of money but

motor manufacturers efforts to clean up their products, but it would also cause many state governments grave problems in meeting other standards specified by the clean air act. He thus refused to entertain the idea of yet another delay.

As for the question of sulphuric acid emissions, that has already caused a split within the Environmental Protection Agency and raised some genuine fears that the catalyst may cause almost as many problems as it solves. The problem is the catalytic converters oxidise not only carbon monoxide and hydrocarbons to carbon dioxide and water, but they also oxidise some of the sulphur in gasoline to sulphur trioxide, and that could result in dangerous levels of sulphuric acid and sulphates in city air.

The problem first came to light earlier this year, and it prompted the EPA's director of research and development to suggest in an internal memorandum that the introduction of catalysts should be delayed until the problem has been given further study. According to the EPA's latest estimates, cars equipped with catalysts will spew between 3 and 5 times more sulphate into the atmosphere than cars not equipped with converters. Mr Train also stated at the hearings that EPA scientists have concluded that unless a mechanism is developed to control sulphate emissions, "more than one model year of cars equipped with catalysts could result in ambient levels of sulphates reaching levels at which recent studies suggest there will be adverse health effects". The EPA will soon be releasing a technical report on the matter, but in any case Train emphasises that if a problem does arise, there will be ample time to find a solution before there is a public health risk. Moreover, Mr Cole testified that "our (GM's) tests and atmospheric modelling show that while there may be some possibility, there is little probability that roadside atmospheric levels of sulphates from catalyst equipped vehicles by themselves will reach any threshold health levels".

But it is on the question of petrol consumption that General Motors testimony was most seriously out of line with that of the other two motor manufacturers. Until recently, all three car makers have been arguing that the exhaust catalyst will greatly increase fuel consumption, a fact that will not do much to help solve the energy crisis. But, much to the dismay of Ford and Chrysler, Mr Cole told the Senate committee that General Motors' cars equipped with catalysts to meet the 1975 emission standards will consume on average 13% less fuel than models being sold this year. To be sure, part of the reason for the dramatic drop is explained by the fact that GM, along with other manufacturers, will be pro-

ducing smaller cars, but the statement has clearly cut the ground from under Ford and Chrysler's attempts to ride the energy crisis bandwagon to put public opinion on their side in the battle against the catalyst.

Thus it seems inevitable that catalysts will be fitted to some 60% of all cars sold in the United States next year. But the debate will carry on for years to come.

ROYAL SOCIETY

Future Energy Sources

ENERGY in the 1980s, last week's symposium at the Royal Society, painted several different pictures of future trends. Mr D. Clark of the Central Electricity Generating Board, pointing out that his board is the largest consumer of fuel in Europe, stated that coal will be the board's staple fuel until the 1980s, when oil will become increasingly more important. The future after that will lie largely with nuclear power.

Up to the 1980s, Mr Clark said, the board can use all the coal that the National Coal Board can provide providing the price is right. But nuclear power will quickly become economical for lower load factors than at present. With forecasts based on a 5% growth rate, the year 2000 would see 24% of Britain's energy needs supplied by nuclear power. Towards the end of the 1980s, surplus nuclear generating capacity should be available on enough nights of the year to make energy storage a practicality.

But while coal still has a large part to play, Mr Clark was clearly not entirely happy at the prospect. "It is a fact", he said, "that over the last fifteen years electricity production has been hit a lot harder by stoppages in coal supplies than in oil supplies."

He also suggested that the volume of ordering of new coal-fired plant will be too small for technical innovations of any dramatic kind in coal plant.

Mr Leslie Grainger of the National Coal Board disagreed. By his calculations, the price of coal has virtually to double before nuclear power becomes competitive for low load generation. Advances in coal utilisation such as fluidised combustion, liquefaction and gasification were all put forward.

"The time has come", Mr Grainger said, "when we should increase the scale of this operation". A demonstration fluidised combustion plant should be built and a fluidised liquefaction plant producing 10 tons a day should be constructed (a half ton a day plant is already running). Coal is going to be very important on a world scale for many decades, Mr Grainger added, and will increasingly be used for conversion to other forms of energy.

Mr E. B. Walker of Gulf Oil Cor-

poration was also optimistic about energy conversion. His interests lay in converting tar sands, oil shales and coal. By 1985, he predicted, 3.75 million barrels of synthetic oil a day will be being produced in the USA. "This will reduce the United States demands on world supplies," he added, "and will therefore greatly strengthen the free world", although it is highly unlikely that any of the synthetics will be exported. Oil extracted with hot water from tar sands is already being produced at the rate of 50,000 barrels a day and Gulf plan to invest \$900 million in a plant that will produce more than twice that amount. Two tons of tar sand produce about one barrel of crude. About the same amount of shale also produce a barrel of oil. But production difficulties in the arid Rocky Mountains mean that there will be long lean times before this source produces large quantities of oil. The cost of these synthetic crudes lies between \$4 and \$7 a barrel at 1970 prices.

Sir Peter Kent, Chairman of the Natural Environment Research Council and a former exploration manager with British Petroleum, warned of the difficulties that have already occurred in bringing North Sea Oil ashore. Pipelines are being laid at twice the usual depth for offshore oil in a stormy stretch of sea and "delays may very well arise".

Happy Hundredth

SIR RICKARD CHRISTOPHERS is 100 next Tuesday, November 27.

He started his scientific career in 1898 as a member of the Malaria Commission, jointly appointed by the Royal Society and the Colonial Office. Ronald Ross had just published his classical work on the mosquito as vector and Christophers, with his deep understanding of insects, was able to exert an enormous influence on the study of diseases borne by mosquitoes. He worked largely in India until 1930 and then returned to London to continue at the London School of Hygiene and Tropical Medicine. On retirement in 1938, he moved to Cambridge and spent part of the war working on insect repellents. From his reports to the Malaria Committee (1900-02) to his 700-page volume *Aedes aegypti*—the Yellow Fever Mosquito (1960) his publications have been of the greatest distinction.

Sir Rickard finally moved to Dorset in 1963 where he spends much of his time gardening. A full tribute appears in *Trans. R. Soc. trop. Med. Hyg.*, 67, 729 (1973).

Short Notes

Population Dilemma

"We must reduce, halve and eventually reverse the present population growth rate." These were the words used in London on Wednesday by Mr Ron Dick, director of Population Countdown, at the start of the organisation's campaign for World Population Year.

Population Countdown aims to raise £150,000 during 1974—World Population Year. The money will be spent on supporting family planning projects throughout the world as well as on making the people of Britain aware of the world's growing population.

Between now and the end of the year Population Countdown will spend £12,000 on advertising in Britain. This money, Mr Dick said earlier this week, has come from a "special donor".

Less than 15% of the money collected by the organisation will go on overheads according to Mr Dick. The eventual aim of the campaign is to raise £1 million a year by 1977-78. During 1974 Mr Dick hopes to set up about 100 local groups throughout Britain to help with the appeal.

Population Countdown is a revamped version of an organisation set up by the Family Planning Association two years ago. In its old form the organisation was not too successful in raising money. But Mr Dick is confident that Population Countdown will meet its stated aims.

In the wake of the flood

THE *Financial Times* may have informed its readers in headline last week that the return of the horse is not the answer to Britain's energy crisis, but other organisations are not so bashful. The Inland Waterways Association has seized the chance of Arab oil embargoes to inform the government that its duty is to "consider methods of reducing our consumption of fuels without jeopardising our industrial viability. Transport, accounting for over one-fifth of our total energy consumption, offers the possibility of such economies". Quoting a 1972 report from Oak Ridge National Laboratory in the United States the association claims that waterways are four times more efficient than roads in terms of fuel consumption.

The Europeans are well aware of the advantages of water transport, the association says. "We ask that the Government, in the interest of fuel economy should update transport investment policy to include a realistic assessment of inland water transport on major new or enlarged waterways".

Less labour. less pollution. less noise.

less road congestion and lower freight rates are the advantages. Can the government refuse?

Indian-Soviet Collaboration

THE plans for launching an Indian research satellite by a Soviet rocket from a base within the Soviet Union are now past the first stage, according to Academician Boris N. Petrov, Chairman of the Interkosmos Council. The organisational basis for the joint project has been established, and the working plans completed. Now all that is necessary, it would seem, is for the satellite to be built.

According to Academician Petrov, "dynamic and static tests on a volume-weight mockup" of the satellite are now under way. The Soviets will provide the rocket—which will be similar to those used to launch the joint Comecon "Interkosmos" satellites. They are also assisting the Indian designers with certain auxiliary systems and elements for the satellite itself. According to the Indian director of the research team, the satellite is intended to monitor solar neutrons and gamma-rays, X-radiation of cosmic origin and also to investigate the ionosphere. Flight control and telemetry will be carried out from bases in both the Soviet Union and in India. The satellite is envisaged by the 200-strong Indian team as only the first step in an extensive space research programme, which will eventually cover applications to meteorology, communications, navigation and mineralogical surveying.

Law of the Sea

A FINAL date has been fixed for the full United Nations Law of the Sea conference that should resolve many questions about territorial waters, patrimonial seas, the law of the high sea, pollution matters and the freedom of oceanography. The conference will get under way on June 20, 1974, at Caracas in Venezuela and is due to last ten weeks. The venue has been changed from Santiago following the recent Chilean coup. The USSR, among other countries, was not prepared to go there.

Neanderthal Remains

EXCAVATIONS at the palaeolithic site of Belogorsk (Crimea) are yielding further Neanderthal remains. Last year, part of the skull of an 11-12 year old child was discovered; further excavations have now revealed a femur, a radius, several vertebrae, and hand and foot bones. Interviewed in *Pravda* (November 12, 1973), Professor Vsevolod P. Yakimov, Director of Moscow Univer-

sity's Institute of Anthropology, said that the new finds probably came from the same skeleton as the skull. On the basis of preliminary investigations at the Institute, he assigns the burial an age of some 50,000 years. Excavations at Belogorsk, which were begun in 1971 by the Academy of Sciences of the Ukrainian SSR, have also yielded mammoth, horse, fox and wolf bones, as well as flint implements.

Blessing Bessborough

THE Institution of Civil Engineers has decided that the Bessborough Report on the Research Associations is, by and large, a good one. The institution has sent its comments on the report to the government and particularly welcomes the proposal that a Board of Industrial Research and Development should be formed with a standing similar to the research councils.

The establishment of the board, the ICE says, would allow coordination over the wide areas of interest that the forty-odd research associations cover. Integration of this research with the research councils and the government research establishments should also be possible.

The institution does, however, sound several warning notes. Increased research and development in the construction field would produce benefits far greater than the extra cost while ocean engineering in particular needs support.

The institution is also eager—along with the Bessborough committee—that more contract research from industry should be placed with the research associations.

More Sandwiches

SANDWICH courses are to come under investigation by a working party set up by the Universities, Polytechnics and Industry Committee.

The setting up of this group has been precipitated by a feeling in industry and in the education world that the increase in training places is not keeping pace with the growth of sandwich course places in the further and higher education sectors.

The group will consider, in general terms, the value of the sandwich course scheme. It will also investigate the future development and expansion of courses, the concomitant need for increased provision of industrial training places, and finance and long term policy in this area.

Dr G. Tolley, Principal of Sheffield Polytechnic, will be the group's chairman.

NEWS AND VIEWS

Redshifts of Quasistellar Objects

THE physical nature of quasistellar objects is as puzzling now as it was 10 years ago when their large redshifts were discovered. Within 3 years of those first redshift determinations the difficulties encountered theoretically in explaining the observed radio and optical properties of the QSOs, if they were indeed at the enormous distances derived cosmologically, had been clearly laid out. Attempts were made to find alternative explanations for the redshifts, in terms of local objects exploding outward from our Galaxy at relativistic velocities, or collapsed objects whose radii had shrunk to near the Schwarzschild limit so that huge gravitational redshifts were present. But these theories were unsatisfactory either on energetic grounds or because of lack of a physically viable model of such an object near the limiting Schwarzschild radius.

A small minority of workers have maintained a sceptical attitude toward the hypothesis that the QSO redshifts are cosmological in origin, produced by the expansion of the Universe. These workers have mostly accepted that no viable alternative theory for the redshifts exists at present, and they have either pressed for additional observations along any lines that appeared promising for settling the controversy, or they have attempted to devise and carry out such observational programmes themselves, or they have made attempts toward devising alternative theories. But above all they have tried to persuade workers to keep an open mind on the question and, especially, not to ignore any data which pointed toward non-cosmological redshifts.

The large majority of astronomers, however, has adhered to the cosmological hypothesis, because this works well for normal galaxies, and because any alternative hypothesis would involve some radical new thinking.

Unfortunately, it has been very difficult to devise observational tests to give a conclusive answer, because most have had to be based mainly on statistical arguments, or on a painstaking and time-consuming search for luminous connections between objects of different redshifts. To collect enough data when time on large telescopes is in great demand is a real problem. The lack of precision in radio source positions has also led to a considerable amount of wasted telescope time.

It is therefore very interesting that astronomers seem at last to be within shooting distance of making some crucial tests. This has come about mainly because of the recent dramatic improvement in the accuracy of radio positions, so that errors are down to 2 arc s or better in some cases, through work at Molonglo, Cambridge, Malvern and Jodrell Bank, and other radio telescopes now starting precision work.

Two exciting pieces of optical work, made possible by these improved positions, are reported in this issue of *Nature*. The first concerns the discovery of a second double QSO with very discrepant redshifts (Wampler *et al.*, on page 203), a joint result by optical workers at Lick Observatory and Hazard on the radio side. The first pair of QSOs with discrepant redshifts, discovered some time ago by Stockton, were 35 arc s apart, but the new pair are at only 5 arc s separation. There is in

addition a faint extended object very near, and the radio source is double with one component coinciding with the brighter of the QSOs. Such a configuration is highly suggestive of physical connection. The authors conclude that "our observation of a close pair of QSOs with discordant redshifts is unlikely under the cosmological hypothesis" and "we believe that these observations add support to non-cosmological theories of redshifts". They also point out some interesting near-coincidences in wavelength: if the brighter and fainter QSOs are a and b , $(1+z)_b \approx 2(1+z)_a$; an absorption feature appears in b very near the wavelength at which strong MgII2800 emission occurs in a but it is probably the CIV1549 doublet at a lesser redshift than the emission-line redshift in b . Finally, there is an emission in a at the same wavelength as strong CIV emission in b . The authors conclude that these all represent "either an unfortunate coincidence or a profound mystery".

The second paper (Hazard *et al.*, on page 205) is joint work by radio and optical astronomers at Hale and Lick Observatories. With the improved radio positions, a search was made for close groupings of blue stellar objects coincident with a radio source and with three or more galaxies near the BSO. The important point is that it was not known during the search whether the BSOs were QSOs or, of course, what their redshifts were. Previous work in which QSOs had been found in close proximity to galaxies had been of two sorts. Burbidge *et al.* had found four (and later a fifth) 3C QSOs lying close to fairly bright galaxies of very different redshifts, a result which yielded high statistical significance, but this result concerned strong radio sources and bright galaxies.

Several other workers have looked for faint groups or clusters of galaxies near QSOs of small redshift. Since the QSO redshifts are known and selected in advance, and since galaxy groupings selected are in the right magnitude range to have redshifts of approximately the QSO value, the investigations, which yielded galaxy redshifts agreeing with the QSO redshifts, were of course clearly biased toward finding support for the cosmological redshift hypothesis, as Hazard *et al.* pointed out. Their investigation is unbiased, and the results are very interesting.

Of four sources selected for study, one was in fact the double QSO described earlier. But in all the other three cases, the fact that the BSO proved to be a QSO of large redshift, obviously much larger than those of the nearby galaxy groups as indicated by their magnitudes, is most intriguing.

The authors point out that no statistical conclusions can be drawn with so few samples, and conclude by leaving open the question of the nature of the redshifts. But one may at last hope for a resolution of the problem; because of the new accurate radio positions, optical observers can spend telescope time examining all BSOs near a radio source and even objects of neutral or reddish colour. In this reviewer's opinion, the case for non-

From Cyclic AMP to Cyclic GMP

CYCLIC AMP (3',5'-adenosine monophosphate) is now biochemical folklore and occupies the same hallowed position as its precursor, ATP (adenosine triphosphate). After a humble birth only 16 years ago, as a curiosity in Sutherland's work on the regulation by adrenaline of hepatic glycogen metabolism, by 1965 it was hailed as an almost universal 'second messenger' for hormones. Since then there has been no major biochemical regulatory event which has not been thought to be mediated by means of cyclic AMP (more than 2,000 papers, a dozen books on cyclic AMP this year and one more serial publication—*Recent Advances in Cyclic Nucleotide Research*—to add to the librarian's shopping list). Even if some of the hypotheses on the role of cyclic AMP are still questionable, this cyclic nucleotide has opened up new areas of research—phosphokinases and protein phosphorylation, gene activation in bacterial adaptation, cellular aggregation and slime mould differentiation, to quote only a few. What has attracted little attention during these past 5 or 10 years of intense activity are regulatory events in which cyclic AMP seems to have no part to play. Quite recently, however, a more interesting story than was imagined only a couple of years ago is emerging and this is where cyclic GMP (3',5'-guanosine monophosphate) comes in.

Already in 1969 Sutherland's laboratory had shown that cyclic GMP compound is present in urine and tissues of a variety of animals (Hardman *et al.*, *J. biol. Chem.*, **244**, 6354; 1969). It is interesting that tissues with relatively small concentrations of cyclic AMP, such as brain, testis and lung, are rich in cyclic GMP. Because of cyclic AMP's initial association with hormone research, the first indications that something important still lay concealed also arose from investigations on hormones. One can arbitrarily classify hormones into two categories: (1) those that act by controlling cyclic AMP activity in their target tissues, such as adrenaline, glucagon and almost all pituitary and hypothalamic polypeptide hormones; and (2) those that do not, such as steroid hormones, thyroid hormones, insulin and plant hormones.

It is studies on this second class of hormones that have yielded one of the clues to the involvement of cyclic GMP in biological regulation as, for example, the recent observation that insulin leads to increased activity of cyclic GMP in adipose and liver cells (Illiano *et al.*, *Proc. natn. Acad. Sci. U.S.A.*, **70**, 2443; 1973). Different groups of workers have also demonstrated that cyclic GMP when added to isolated tissues and cells has profound metabolic effects which could not be produced with cyclic AMP. Of particular importance are the findings of Greengard's group who showed that in lobster muscle and neuroblastoma cells there exist two quite distinct protein kinases—one dependent on cyclic AMP and the other on cyclic GMP (Kuo and Greengard, *J. biol. Chem.*, **245**, 2493; 1970). These workers, who have considerably advanced knowledge of the role of cyclic nucleotides in neural function, were also able to show that the cerebellum was particularly rich in a guanyl cyclase activity (conversion of GTP to cyclic GMP) and most tissues examined so far have now been shown to contain this enzyme. Several properties of this enzyme, not least its weak association with membranes, seem to be different from those of the classical membrane-bound adenylyl cyclase system which is

(Hardman and Sutherland, *J. biol. Chem.*, **244**, 6363; 1969).

As with progress in many other areas of biochemistry, the speed and accuracy with which a new concept can be tested often depend on how successfully analytical technology could be tailored to tackle new questions. This is true for cyclic GMP. The extremely small intracellular amounts of this nucleotide (10–100 fmol g⁻¹, or 10–50 times smaller than those of cyclic AMP) meant that, until recently, the assays were extremely laborious and often unreliable. The radioimmunoassay method (Steiner *et al.*, *Adv. Biochem. Psychopharmac.*, **3**, 89; 1970), now tried out in many laboratories, has, however, opened the way for eventually establishing cyclic GMP as an important intracellular mediator of metabolic and growth regulation, perhaps of the same importance as cyclic AMP.

Thus, thanks to a reliable assay for cyclic GMP, several interesting differences between the two cyclic nucleotides are now apparent. First, hormones like insulin, cholinergic (acetylcholine) or other agents (histamine) important in neural function, and lentil mitogens, all of which are known not to depend on cyclic AMP for their action, now seem to act by way of cyclic GMP. Second, it is becoming more and more apparent that there exist not only distinct cyclases, but also distinct phosphodiesterases and cyclic nucleotide binding proteins (or phosphokinases) which suggests that sites of synthesis, degradation and action are not the same for the two cyclic nucleotides. Perhaps of even greater interest is the suggestion that the high concentrations of one cyclic nucleotide prevent the formation, metabolism or action of the other. Evidence for this is not always firm or unanimously accepted; for example, the suggestion that cyclic GMP may cause a reduction of intracellular concentrations of cyclic AMP by activating the specific phosphodiesterase for cyclic AMP is disputed.

Whatever will be the more acceptable conclusion for the above particular phenomenon, Goldberg at the University of Minnesota has been fascinated by the mutual antagonism between the two cyclic nucleotides and has recently formulated an interesting hypothesis, in which he and his collaborators rationalise the diverse effects of these two key purine metabolites. In a review which is to appear in volume 3 of *Recent Advances in Cyclic Nucleotide Research*, Goldberg and his colleagues say that a signal such as a hormone or a neurotransmitter may exert 'monodirectional' control of generating either cyclic AMP or cyclic GMP, with each nucleotide having a separate stimulatory effect. It seems that all such 'monodirectional' systems (for example, the regulation of salivary gland secretion by parathyroid hormone) are for some reason calcium-dependent. Goldberg and his colleagues also offer a 'bi-directional' model of control embodied in the 'dualism' or Yin-Yang hypothesis, based on an analogy from the classical Chinese precept which states that for every point of stimulation (say, of a nerve, as in the practice of acupuncture) there is a corresponding point of inhibition or suppression. Thus in a bi-directional system, stimulation or inhibition of a process is achieved by a simultaneous drop in concentrations of cyclic AMP as those of cyclic GMP increase, and indeed this seems to be the case in a variety of systems that these workers have examined.

The dualism of Yin-Yang hypothesis is also supported

by observations that cyclic GMP promotes events in the cell that are antagonistic to those mediated by cyclic AMP. Conversely, artificially increasing the intracellular concentration of cyclic AMP, as with theophylline, led to an abolition of the response to cyclic GMP whether given exogenously or generated within the cell. These observations are not often easy to record because the changes in amounts of cyclic GMP are very low and transitory and because of a further variable, calcium, which is required for most cyclic GMP mediated effects. Nevertheless, in making these observations Goldberg and his associates have laid open for future experimentation many interesting regulatory systems. In a recent paper by Goldberg's group (Estensen *et al.*, *Nature*, **245**, 458; 1973) it is shown that movement of leukocytes, which is known to be inhibited by cyclic AMP, is markedly promoted by cyclic GMP. They propose that chemotactic agents like cytochalasin B, phorbol myristate acetate (PMA) or acetylcholine may act by potentiating the action or increasing the concentration of cyclic GMP. Furthermore, anybody dealing with such important phenomena as cell proliferation, viral transformation of cells, induction of immune response, action of nerve growth factor, in which cyclic AMP has an inhibitory effect, ought to examine a positive involvement of cyclic GMP.

It is, after all, not very long since interest in cyclic GMP has been gathering momentum so that many of the observations noted here still await rigorous confirmation. Among the more important issues that will soon have to be settled are:

- The location of guanyl cyclase. It is believed that adenylyl cyclase is situated within the close proximity of

the receptor for the hormone, or other biologically active agent; within the plasma membrane of animal cells. If guanyl cyclase turns out not to be a membrane enzyme, then it raises the interesting question of the nature of its association with the cellular receptor; particularly for molecules such as insulin which are currently thought to act from outside the cell.

- Mere changes in the intracellular concentration of cyclic GMP are not sufficient evidence of a primary regulatory role for this cyclic nucleotide. It is therefore urgent to identify cyclic GMP binding protein(s), and in this context the distinctness of protein kinases dependent on cyclic AMP and cyclic GMP offers a valuable clue. One has here only to consider how valuable the recognition of cyclic AMP binding protein has been to establish the role of cyclic AMP as a mediator of gene activation in *Escherichia coli* (Pastan and Perlman, *Adv. Cyclic Nucleotide Res.*, **1**, 11; 1972). There is also the subsidiary issue of clarifying the role taken by calcium in the action of cyclic GMP.

- The more general biological problem of key metabolites, or 'second messenger', a term first coined for cyclic AMP, that have to be generated for a regulatory agent to exert its action will have to be considered. Will it stop at cyclic GMP or will there be a flood of similar intermediate control elements? (At least the cyclic pyrimidine monophosphates seem to have been ruled out.)

Answers to all these questions may require some patience, but judging from the exponential rate at which publications are appearing, it will not be long before cyclic GMP is established as the second 'second messenger'.

Immunopathology of Parasitic Infection

MOST parasites are capable of evoking immune responses in their hosts but these are seldom effective in eliminating the infection because parasites have evolved a number of ways of evading the immune response and its consequences. Some, like the African trypanosomes and malaria parasites, continually change their antigens and outwit the immune response in this way. Others, like the schistosomes, incorporate host material into their surfaces and thus become immunologically invisible. A major problem in many parasitic diseases is that not only is the immune response ineffective but it may also give rise to a variety of pathological conditions. The immune response may therefore be counterproductive. Glomerulonephritis is a serious consequence of both African sleeping sickness and malaria and is thought to be initiated by the deposition of antibody-antigen complexes in the kidneys. The localised immune responses evoked to deal with these complexes have no effective role in protection. The parasites continue to multiply elsewhere in the body and soluble antigens pass into the circulation to give rise to the antibody-antigen complexes in the glomeruli.

The problems brought about by an immune response which takes place away from the site of infection also occur in schistosomiasis. The adult worms live in mesenteric blood vessels and their numbers are controlled by an immune response which has been completely manipulated by the parasite. The worm takes up host antigens from the blood and incorporates them into its

surface. Sheathed in host antigens, the worm is immunologically invisible but continues to pass antigens into the blood stream to elicit an immune response which is effective only against new invading forms as they migrate through the skin and underlying tissues of the host. This kind of response should produce a well balanced host-parasite relationship and prevent overcrowding of the worms. Crofton (*Parasitology*, **62**, 179; 1971) has pointed out that helminth infections tend to be overdispersed and most hosts harbour relatively small and easily tolerated worm burdens. In such circumstances only the very heavily infected hosts would be expected to die and most would not be unduly inconvenienced by the infection.

Unfortunately there is a major complication in schistosome infections. The female worms release large numbers of eggs which enter the blood stream and lodge in the small blood vessels in a variety of tissues especially the spleen, lungs and liver where up to 10,000 per gram may be found. These eggs cause granulomas to form. The granulomas begin as reactions involving macrophages, lymphocytes and eosinophils and later become fibrous. The formation of granulomas eventually leads to liver obstruction and liver function failure and, in experimentally infected animals, the liver may reach double its normal size. The granulomas are obviously very important in the pathology of schistosomiasis.

For many years it was widely held that the granulomas were the result of a cellular response to irritation but it is now known that their origin is immunological. This

realisation has gradually emerged from a carefully directed research programme extending over 16 years by K. S. Warren of the Case Western Reserve School of Medicine and a number of collaborators. Warren has summarised the evidence that granuloma formation results from a delayed hypersensitivity reaction (*Trans. roy. Soc. Trop. Med. Hyg.*, **66**, 417; 1972) and has since extended these findings with the collaboration of D. L. Boros who originally joined him as a post-doctoral research worker. On page 224 of this issue they describe how they, and Pelley, have isolated granulomas *in vitro* and have extracted from antigen stimulated granulomas a substance that inhibits the migration of macrophages and which they identify as a lymphokine. In another paper Boros and Warren (*Immunology*, **24**, 511; 1973) describe how the intravenous injection of bentonite particles impregnated with the antigen elicits granuloma formation in the lungs of sensitised mice.

The antigen is a soluble substance released from the egg. After the egg is laid embryonation occurs and this is accompanied by the liberation of enzymes and soluble antigens (which may be enzymes). The egg acts as a focus for the granuloma. Macrophages enter the immediate vicinity of the egg and come under the influence of the lymphokine and are unable to move away. In most bacterial and fungal infections this kind of local reaction isolates the invading organisms which are then phagocytosed by the macrophages. In schistosomiasis, however, a granuloma 100 times the size of the egg is formed and this is gradually replaced by fibrous scar tissue. Boros and Warren have also found that bentonite particles impregnated with mycobacterial and histoplasma antigens induce granulomas in animals sensitised with homologous antigens but not heterologous ones.

It is clear from these experiments that the pathology of schistosomiasis is not unique and comparable situations probably exist in a number of parasitic infections. The existence of non-protective delayed hypersensitivity states in parasitic diseases makes vaccination attempts potentially dangerous procedures which might even lead to immunological enhancement. The World Health Organisation (*Tech. Rep. Ser.*, No. 519, *Cell Mediated Immunity and Resistance to Infection*; 1973) is fully aware of this problem and as more information about

immunity to parasitic diseases accumulates the possibilities of developing useful methods of immunisation fade further and further into the distance.

CONTRACEPTION

How Safe is Safe?

from a Correspondent

How safe is the 'safe' period as a means of contraception? This will depend among other things upon how long the ovum and sperm can exist in the reproductive tract without loss of the ability for fertilisation and how fixed in the menstrual cycle is the time of ovulation. Can ovulation in normally menstruating women occur at times other than at about mid-cycle? Can it be induced, or can spontaneous ovulation be hastened, by coitus? Although coitus-induced ovulation occurs in many species it is not usually considered to be a phenomenon in humans.

Jöchle (*Contraception*, **7**, 523; 1973) has now reviewed the evidence relating to this question. The length of the luteal phase of the cycle seems to be fairly fixed at about 14 days; variations

in menstrual cycle length usually result therefore from variability of the follicular phase. It is known that hypothalamic-pituitary-ovarian function can be modified by environmental change resulting in inhibition of ovulation and a consequent change of menstrual pattern or the complete absence of menstruation (psychogenic amenorrhoea).

The possibility exists therefore that other environmental changes might stimulate pituitary gonadotrophin secretion and produce ovulation. That ovulation can occur at times other than mid-cycle has been suggested by examination at autopsy of ovaries and uterus and calculation of the time interval in which ovulation must have occurred. When this interval was related to the time of menstruation of the previous cycle the results suggested that ovulation could occur at any time in the cycle. Similar observations made at surgical operations also suggested that ovulation could occur on any day of the first half of the cycle.

Evidence in support of coitus-induced ovulation was obtained from two sources. (1) Conceptions resulting from rape, using data only from patients for whom reliable information could be

Haemin Selectively Stimulates α Globin Synthesis

THE study of the role of haemin in protein synthesis is interesting because it provides evidence that some regulation takes place at the level of translation. When haemin is added to a cell-free system containing globin messenger RNA globin synthesis is stimulated, but so too is the synthesis of endogenous proteins. By contrast, when its effect is studied in an *in vitro* system (for example, when globin mRNA is injected into *Xenopus* oocytes), only the synthesis of globin is increased.

In *Nature New Biology* next Wednesday (November 28) Giglioni *et al.* describe some experiments designed to help elucidate the function of haemin in globin synthesis. Using the oocyte system they have found that in conditions of rabbit globin mRNA saturation there is about four times more β globin than α globin synthesised. By increasing the amount of haemin added to the system α globin synthesis is proportionally increased until a haemin concentration of 30 μ M when the ratio remains constant with α globin nearly 40% of the total globin synthesised in the system.

Endogenous protein synthesis is unaffected even at high haemin concentrations. At subsaturating levels of mRNA an $\alpha:\beta$ globin ratio of 1:1 can be achieved by injecting haemin into the oocytes, and if globin mRNA rich in α messenger is used more α than β is

From these results alone, the possibility cannot be excluded that haemin affects the recovery of the globin chains, after their release from the ribosome, rather than their synthesis. The results of control experiments, however, make the first suggestion extremely unlikely. Control experiments also exclude the possibility that the low α to β ratio, in the absence of haemin, is due to a delay in the release of α chains relative to β chains.

It seems clear that in this system haemin controls the synthesis of α but not β mRNA. The authors suggest that the mRNAs for α and β globin compete for some component necessary for their translation (but not that of endogenous mRNAs), and that the effect of haemin is restricted as soon as mRNA concentration becomes saturating.

It is difficult to know how far these results can be extrapolated to explain the action of haemin in intact reticulocytes. If reticulocyte-rich blood is incubated in the presence of lead the synthesis of haemin is inhibited and this is followed by a 90% reduction in globin synthesis. The absence of haemin in the oocyte system does not have such a depressing effect. In haemin-free reticulocytes, however, the α globin synthesis is inhibited more than that of β globin so that in this important aspect the oocyte system and reticulocytes are

obtained about the menstrual cycle, its pattern and time of the last menstruation before rape. Analysis of these conceptions showed that 33–46% of all conceptions took place during the safe period after menstruation, 10–30% during the safe period before menstruation and about 8% during menstruation itself. Thus fertility seemed to be elevated during most of the first half of the cycle and not only at about mid-cycle. (2) Conceptions resulting from limited exposure. An evaluation of 100 carefully selected cases showed that the risk of conception during the first and last four-day period of the menstrual cycle could be as high at 10% of the risk of conceiving during the mid-cycle period. In an investigation involving 241 British women who were using the basal body temperature method for birth regulation and who were studied throughout nearly 2,000 cycles, the conception risk was highest between days 10 and 12 of the cycle. The risk, however, was still very high at any time from day 5 to day 15 and, although markedly reduced during the luteal phase, the risk could still be up to 5%.

The value of this type of evidence depends on the surety that no other cohabitations took place during the period in question. Conceptions occurring in women with amenorrhoea have also been reported, although such evidence is difficult to evaluate in view of the possible spontaneous ovulation which occurs occasionally in these subjects.

Jöchle, after reviewing the evidence, concludes "the possibility of coitus-induced ovulation in humans should no longer be denied" and consequently it makes one sceptical whether the rhythm method of contraception can ever be completely successful. Most of the evidence quoted, however, is circumstantial; much less doubtful evidence is required before coitus-induced ovulation can be accepted as a reality.

PROTEIN SYNTHESIS

Ribosome Attachment

from a Correspondent

JOAN ARGETSINGER STEITZ has continued her studies on the control of the initiation of protein synthesis in the small RNA bacteriophage called R17. She had previously determined the nucleotide sequence of the three initiator fragments of the RNA, each about thirty residues long, which are responsible for the attachment of the RNA to the ribosome of the infected cell. These three fragments correspond to the three proteins, the coat protein, the replicase protein and the A protein, synthesised by the RNA.

She has now studied the interaction of

fragments rather than the intact 3,300-residue long RNA molecule, with ribosomes (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 2605; 1973.) Surprisingly, only the initiator fragment for the A protein has the ability to bind *in vitro* to either *Escherichia coli* or *Bacillus stearothermophilus* ribosomes. By contrast, the initiator fragments for the coat and replicase protein do not bind significantly. She concludes that the RNA ribosome binding site of the A protein seems intrinsically to be a good initiator, whereas efficient recognition of the short coat and replicase regions requires the participation of some portions of the remainder of the phage RNA molecule.

Steitz suggests in a discussion that the influence of these other parts of the RNA on the specific initiator regions is probably exerted by a control of the exact three-dimensional structure of the binding sites. The inability of the coat protein site to bind, however, was surprising as it is known to form a stable hairpin-looped secondary structure with an A-U-G codon (specifying the first amino acid, formyl methionine, of the coat protein) exposed in the loop. Presumably therefore this loop formation cannot be sufficient for recognition by ribosomes. In fact, as such a stable hairpin-looped structure is unlikely to be present for the A protein site in either the fragment or the intact molecule, Steitz suggests that the function of

the remainder of the R17 RNA molecule may actually be to facilitate opening of looped structures during ribosome attachment.

INSECT PHYSIOLOGY

Juice Extractor

from our Insect Physiology Correspondent

SINCE Léon Dufour in 1833 published his observations on the anatomy of the gut in the Homoptera, it has been known that most members of this group of plant-sucking bugs have a more or less complicated association between the commencement of the midgut and its termination, in conjunction with the Malpighian tubules, in the ileum (the first segment of the hindgut). Dufour named this arrangement the 'filter chamber' in which, as he supposed, the copious watery contents of the plant juices were filtered off directly to the hindgut, while the nutrient material was carried on to the midgut. But there have been no experimental studies carried out to substantiate this idea.

A physiological study of the kind required has now been made by Cheung and Marshall (*J. Insect Physiol.*, **19**, 1801; 1973) on a variety of cicadas in Hong Kong and Australia. Cicadas feed on xylem fluid which is hypotonic to the haemolymph of the insect and contains high concentrations of potas-

Soft Gamma-ray Bursts from Compact Objects

THE energetic soft γ -ray bursts observed by the Vela satellites could result from fleeting episodes of accretion on to nearby compact objects—neutron stars or black holes. The sixteen or so bursts seen so far last typically for 1 to 10 s and show significant structure on time scales as short as 100 ms. The uniform distribution of possible source locations over the sky suggests that the sources are local.

Taking the typical distance as 100 pc, the luminosity during each burst is about 10^{37} erg s⁻¹, with the radiation spectrum peaking at around 100 to 400 keV. In *Nature Physical Science* next Monday (November 26) Lamb, Lamb and Pines emphasise that these time scales and luminosities are characteristic of the compact galactic X-ray sources, which are thought to be neutron stars or black holes continuously accreting matter from their close stellar companions.

The space density of these X-ray sources is less than 10^{-8} pc⁻³. The authors, however, estimate the sources of the γ -ray bursts to have a space density of about 2.5×10^{-2} pc⁻³ and argue that the space density of binary systems containing a compact object

The amount of matter that has to be accreted in order to liberate the required amount of energy per burst is about 10^{16} g. The largest solar flares, occurring every 5 to 20 yr, eject a mass of about 10^{16} g at a speed of about 1,500 km s⁻¹. Thus if the binary companion of the compact object undergoes similar flaring activity—perhaps on a slightly larger scale, but not necessarily as violently as flare stars—accretion of a part of this ejected material can neatly account for the observed properties of the soft γ -ray bursts. Since the ejection velocity is so supersonic, the accreted material need have little angular momentum with respect to the compact object, and so is able to fall straight on to the surface without having to go through the relatively slow process of forming an accretion disk.

In ordinary X-ray sources with temperatures corresponding to about 10 keV, the energy liberated by the continuously infalling material is more or less thermalised on the surface. It seems plausible that the energy liberated by a single blob of matter falling on to the surface will be less completely thermalised and will, therefore, be radiated at the higher temperature corres-

sium, sodium, calcium, magnesium, chloride and phosphate ions. The urine contains the same ions in slightly lower concentrations. Amino acids and sucrose are present, and traces of amino acids persist in the urine. If xylem fluid is injected into the oesophagus there is an immediate ten-fold increase in the flow of liquid in the ileum. Meanwhile the osmotic pressure in the xylem fluid within the filter chamber rises, while the osmotic pressure in the anterior part of the ileum rapidly falls.

As the residual fluid passes on down the midgut, water, nutrients and ions are absorbed into the haemolymph and divalent ions are stored in granular form in the walls of the mid-midgut. Ions may be transferred from the haemolymph into the posterior tubular midgut, where the osmotic pressure of the contents is high in the post-feeding stage. Certainly the Malpighian tubules secrete a fluid which is rich in potassium (42 mM/l) and sodium (15 mM/l) and is hypertonic to the blood. Thus when the contents of the terminal midgut and of the Malpighian tubules reach the filter chamber and become intimately associated with its walls, they have an osmotic pressure considerably higher than that of the xylem fluid as it enters the filter chamber proper. Passive osmosis will therefore occur and water will thus be carried across the walls into the commencement of the ileum. Potassium and to a lesser extent sodium, as in other insects, are actively reabsorbed in the lower segments of the ileum and thus provide the recirculating ions needed to keep the machine going.

These results strongly suggest that Dufour was right and the chamber really is a 'filter chamber', and that the ionic concentrations needed to sustain its operation are the result of secretory activity elsewhere in the Malpighian

SILICA

Light Thrown on Charge Transport

from our Solid State Physics Correspondent

THE observation of currents in insulators has always been a difficult task and thus it is only recently that it has been confidently asserted that electrons travelling in solids with wide band gaps do so according to roughly the same laws as those in semiconductors, and that, given the necessary boost, electrons in solid dielectrics can be raised from the valence states to a conduction band and, in the right material, can then move easily and without undue scattering or trapping over large distances. Such evidence can only be gained by the use of high energy sources of light or particles and, preferably, very short pulses. Spear (see, for example, *Phys. Rev. Lett.*, **25**, 509; 1970) pioneered this work, deducing drift mobilities for electrons in such materials as Pyrex glass. From his technique, however, it was not easy to deduce basic quantities such as carrier lifetime and trapping frequency. Recently, Hughes (*Phys. Rev. Lett.*, **30**, 1333; 1973, and *Proc. Twenty-seventh A. Symp. Frequency Control, Cherry Hill, New Jersey*; June 1973) has greatly reduced the time scale by using very sharp X-ray pulses lasting only a few nanoseconds together with equally fast signal-recording techniques. So, for the first time, a carrier lifetime for silica has been obtained and an interesting array of effects has been revealed.

Application

These experiments are illuminating and important because silica is a particularly useful material both in the research and technological sense. The structure of silica, in crystalline and amorphous forms, has been intensively examined by diffraction techniques and the Si-O bond as a chemical entity is also much studied by organosilicon chemists. Silica is of great importance in technology—its uses range from rugged, expansion-free optics to crystal oscillators; further, silica has recently found new and important uses as a key element in metal-oxide-silicon devices, surface acoustic wave devices, optical waveguides and pressure gauges. Also, being a refractory, insulating material, silica may play a significant part in the building of a nuclear fusion reactor and indeed already provides the most long lived thermal protection for space vehicles exposed to intense radiation in space. The combination of strong piezoelectric response, optical transmission and controlled transport properties may also give silica an important place in optical integrated circuits. Thus, it is important to learn as much as possible about how charges and ions move in this material.

dioxide in thin-film form has been determined to be about 9 eV. It is known that intrinsic d.c. photoconductivity can be induced in the material and that the mobility of electrons is high, by contrast with that of holes which is much lower. The electron mobility in thin-film silicon dioxide is of the order $30 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ (Williams, *Phys. Rev.*, **140**, A569; 1965). This is a very high value for an amorphous material since Mott (*Adv. Phys.*, **16**, 49; 1957) estimates that a typical electron mobility for amorphous materials is about $1 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$. Thus, there is the extra interest of a new measurement of charge transport in a bulk solid—that it may at least confirm or contradict this surprising measurement and, furthermore, allow the measurement to be done on both crystalline and amorphous forms, a comparison not possible with thin-film silica.

A very high peak dose rate of X rays must be used, since, even with, say, $10^{10} \text{ rad s}^{-1}$ of 600 keV photons, the transient currents generated are small (of the order of a few nanoamps) and flow for a very short time (of the order of 10 nanoseconds). These measurements are, however, well within the bounds of the capabilities of Sandia Laboratories. Sandia is, in fact, interested in the possibly catastrophic effect of electric fields that are high enough to produce breakdown in quartz crystal oscillators or pressure gauges. Hughes has been able to distinguish between two forms of decaying current after the X-ray pulse and to distinguish cases in which the drift mobility is field dependent and others in which it is not. This is vital information, since the former condition indicates that many carriers are managing to transit the sample without being trapped, whereas the latter case indicates trap modulation in some samples, from the characteristics of which a carrier lifetime can be deduced. There is also a long lived component of the photocurrent which could represent an important check on a recent theory of radiation-induced ion mobilisation (McCaughan and Murphy, *IEEE Trans. nucl. Sci.*, **NS19**, 249; 1972). The most satisfying result is for very pure amorphous fused silica. As with the thin-film samples already mentioned, Hughes finds the carrier mobility in a bulk fused silica slab to be about $20 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ at room temperature, increasing at lower temperatures to a saturation level of about 40. Not only does this fit well with the thin-film data but also with a theoretical prediction of Lynch (*J. appl. Phys.*, **43**, 3274; 1972) in which the temperature dependence is determined by longitudinal optical (LO) phonon scattering alone and predicts $32 \text{ cm}^2 \text{ V}^{-1}$

also correctly predicts the breakdown strength of silicon dioxide films—another indication that these measurements should rapidly find practical application.

Mobility and Lifetime

Surprisingly, mobility and lifetime are lower in crystalline silica and, although it is difficult to control the incorporation of impurities during the growth of quartz crystals, a correlation of carrier lifetime and mobility with degree of impurity of crystal seems to exist. For example, Hughes finds that lithium-doped synthetic quartz has a higher mobility-lifetime product than the non-doped variety, whereas the synthetic fused silica samples, always much more pure than the flux-grown crystals, typically have twice the carrier lifetime of the crystals and well over twenty times the mobility value. Although the reduced mobility might suggest trapping phenomena as the cause, the mobility exhibits little temperature dependence. Thus, the more likely explanation is some form of impurity scattering, as confirmed in semiconductors. The field dependence of the radiation-induced conductivity again suggests LO phonon interaction as the limiting effect, since the drift velocity saturates at about the levels predicted by Thornber and Feynman (*Phys. Rev.*, **B1**, 4099; 1970), around 10^7 cm s⁻¹.

The question, then, is why an amorphous solid should possess such high mobility—indicating a mean free path of about 40 Å—when, according to most theories of the amorphous state, the mean free path should be of atomic dimensions, on account of the presence of localised states induced by the presence of disorder (see, for example, the studies on amorphous silicon by Spear and Le Comber, *J. Non-cryst. Solids*, **8-10**, 727; 1972). This would seem to confirm the X-ray evidence (Konnert, Karle and Ferguson, *Science*, **N.Y.**, **179**, 177; 1973) that the short-range order in fused silica is very good, the only deviation from order being some variation in Si-O-Si bond angles. This probably means that there is not a large amount of bond strain in the atomic network, therefore the same wide distribution in binding energies found in many amorphous solids does not exist. This could well lead to a major reduction of the 'tail' of localised states normally required to explain the transport and optical properties of compounds like the chalcogenide glasses.

Certainly, the reflectance spectra of fused silica and quartz look astonishingly alike (Phillipp, *J. Phys. Chem. Solids*, **32**, 1935; 1971) and some might say that the high mobility suggests that silica borders on the microcrystalline. But just as melting produces no strong

conductors (see, for example, Adler, *Crit. Rev. solid state Sci.*, **2**, 317; 1971), it may be that electron transport continues to be efficient whenever short range order persists and thus so far the picture of fused silica as an amorphous solid remains. It should also be said that Hughes finds that holes seem to be very firmly lattice trapped and do not contribute at all to the photoconduction. This confirms most previous findings in thin-film silica and lends support to the current theories of space-charge build-up in these materials (see, for example, Zaininger and Holmes-Siedle, *RCA Rev.*, **28** (2), 208; 1967).

Implications

One general conclusion is that it may take as much (or more) trouble and time to obtain insulator crystals free of troublesome impurities as it did for semiconductors especially since, at the moment, there is not as strong a technological motivation for producing them. For those concerned with controlling radiation-induced conductivity (reactor designers and so on) manipulation of impurity scattering may, however, provide a useful tool for reducing unwanted conductivity. Second, one can echo a conclusion of Revesz (*J. Non-cryst. Solids*, **7**, 435; 1972) that the amorphous oxides, nitrides and related glasses might provide a good medium for the basic

study of the amorphous state because they are disordered only in the mildest way possible. Third, low field conduction work has received encouragement from these findings, which have tied together and strengthened some previously intriguing but hardly demonstrable hypotheses on transport in insulators and, incidentally, have annihilated at least one earlier theory of field dependence of mobility in silica (Onnasch, *Phys. stat. sol.*, **38**, 579; 1970).

PALAEONTOLOGY

Fossil Diversity

from a Correspondent

It is widely acknowledged that plate tectonics has had a revitalising effect on many fields of earth science, and nowhere is this more true than in palaeobiogeography, which is the name given to the study of fossil distributions in time and space. Abundant evidence of the burgeoning interest in this subject is provided by the numerous papers recently published in the *Atlas of Palaeobiogeography* (edit. by A. Hallam, Elsevier, 1973), and in two conference symposia, *Organisms and Continents Through Time* (edit. by N. F. Hughes, *Paleont. Ass. Spec. Paper* 12, 1973) and *Implications of Continental Drift to the Earth Sciences*, vol. 1 (edit. by D. H.

Rock of Grenville Age found on Rockall Bank

GEOPHYSICAL evidence suggests that the Rockall Plateau (and thus the Rockall Bank which forms part of it) may be a microcontinent isolated during one of the phases of spreading in the North Atlantic region. Until recently, however, geological evidence for a continental basement structure in the form of granitic or metamorphic rocks on the plateau was not entirely convincing, because, although several dredge hauls had been carried out in the vicinity of the plateau, most of the recovered samples could not be interpreted unambiguously. Moreover, further ambiguity was introduced by the presence of iceberg plough marks around the Rockall bank and evidence of ice-rafted deposition.

This equivocal situation was resolved earlier this year when Roberts *et al.* (*Nature phys. Sci.*, **244**, 21; 1973) reported the results of drilling two outcrops about 100 km apart in the southern section of the Rockall Bank. Granulite facies metamorphic rocks were found at both sites. In one case the hornblende in the drill core (acid granulite) was dated at 1566 ± 33 million years (Loxfordian) and the whole rock at 1670 ± 24 m.y. Thus the presence of continental rocks underlying the Rockall

tension, that the whole Rockall Plateau may indeed be a microcontinent.

But Roberts and his colleagues also proposed that rocks of Grenville age may occur on the southern section of the Rockall Bank—a prediction arrived at by considering the pre-drift reconstruction of the North Atlantic Ocean in the light of the new Loxfordian age. This prediction has now been confirmed by Miller, Roberts and Matthews who report their discovery in *Nature Physical Science* next Monday (November 26). The rock concerned, an andesine-orthopyroxene-biotite-quartz granulite, is that obtained previously by Roberts and his colleagues at the southernmost of their two sites on the southern section of the Rockall Bank.

This age obtained (987 ± 5 m.y.) is the first Grenville age found within the British Isles or west of the Caledonian Front in Europe and suggests that the Grenville Front crosses the southern section of the Rockall Bank, although confirmatory results from other rock samples will be required before certainty can be claimed. In the meantime, however, Miller and his colleagues make a further prediction—that rocks of Grenville age may also underlie parts of the Porcupine Bank or the continental shelf

Tarling and S. K. Runcorn, Academic, 1973). Most of these articles are concerned with patterns of organic provinciality or cosmopolitanism in relation to migrating continents. Another fruitful line of approach, however, has been to consider how fossil diversity, or taxonomic variety, might have been affected by plate movements in the past 600 million years.

Pioneer work in analysing diversity changes through Phanerozoic time in fossil marine invertebrates has been undertaken by the American palaeontologist J. W. Valentine. In a series of stimulating papers during the past few years, he has put forward interpretative models which attempt to relate the diversity patterns recognised to changing configurations of continent and ocean, and changing climate. A particularly commendable feature of his work has been the successful application of modern ecological concepts such as environmental stability to the fossil record.

Valentine recognises a rapid rise in the number of families and genera in the Cambrian and early Ordovician, reaching a maximum in the Devonian, followed by a progressive decline to a minimum in the late Permian and early Triassic. Subsequently diversity

seems to have increased at a high rate through the remainder of the Mesozoic and Cainozoic. The Palaeozoic and Cainozoic provinciality patterns are held to be quite different. During the Palaeozoic the existence of a huge supercontinent, and hence low environmental stability, centred around the South Pole favoured high climatic continentality and a mild thermal pattern of relatively low provinciality, also helping to limit diversity. In the Cainozoic high provinciality (and hence diversity) developed as a consequence both of dispersion of continental masses and stronger latitudinal differentiation of climate. The sharp drop in diversity at the end of the Palaeozoic is attributed to widespread extinction resulting from the creation of the supercontinent of Pangaea, by the suturing of several smaller continents, which led to increased interfaunal competition and to increased seasonal contrasts in climate.

Diversity changes through time can be considered in terms of secular trends and shorter-term oscillations. With regard to the former, Raup (*Science*, N.Y., 177, 1065; 1972) has questioned the pattern of changes outlined by Valentine by drawing attention to several possible time-dependent biases in the data.

To take one example, the chances of given fossil taxa being preserved will depend to a large extent on the chances of their containing sediment not being subject to erosion or metamorphism. Quite simply, these chances increase with decreasing age, hence the sharp and progressive diversity increase in the Mesozoic and Cainozoic could be an artefact, as could the late Palaeozoic diversity reduction, which seems to correlate well with a reduction of volume of marine sediment deposited at that time. Raup proposes an alternative model in which a mid-Palaeozoic diversity maximum is assumed, followed by reduction to an equilibrium level. He has generated a computer model on this basis, with the hypothetical diversity being modified by selective fossil destruction, the probability of which has been calculated to decrease through the course of time.

Raup is probably correct in claiming that Palaeozoic diversities were relatively higher than appear from Valentine's data, and that the strong post-Triassic increase may to some extent be an artefact. Since, by general consent, the end of the Palaeozoic marked a time of mass extinction with its obvious concomitant of reduced diversity, one must react more sceptically to Raup's postulated correlation with reduced marine sediment volume, which may be controlled by the same fundamental cause or be merely coincidental. His criticisms have less bearing, moreover, on the interesting and comprehensive work of Flessa and Imbrie (in the Tarling and Runcorn volume), which is concerned not with secular trends but with oscillations in diversity at intervals of 10 million years.

Flessa and Imbrie apply Q-mode factor analysis to rates of increase and decrease of many fossil invertebrate and vertebrate families, the fluctuations in numbers being treated as a function of rates of origination and extinction. Their analysis confirms earlier, less quantitative notions that the fluctuations of different groups are not random but tend to coincide in time. The conclusion is drawn that correlation with events associated with lithospheric plate movements is sufficiently good to suggest a significant relationship. Flessa and Imbrie go on to develop a predictive model for changing continent-ocean relationships based on the ecologists' well-known species-area equation. Graphs are produced showing the changes in diversity to be expected for a given change of continental area and differing degrees of cosmopolitanism and geographic isolation. In spite of the speculative nature of the exercise and the simplifying assumptions made, their analysis is very enlightening and suggests a promis-

SELENOLOGY

Near-surface Model

from our Geomagnetism Correspondent

ESTIMATES of the physical properties of the near-surface material of the Moon were made even in the days when the only data available were measurements of the brightness temperature of the lunar surface. Thus, for example, Piddington and Minnett (*Aust. J. scient. Res.*, 2A, 643; 1949) proposed that the lunar surface comprises a thin (about 1 mm) layer of fine powder covering a more solid base. Jaeger (*Aust. J. Phys.*, 6, 10; 1953) also concluded that the lunar surface is a fine evacuated powder, or at least acts like one thermally, to which Muncey (*Aust. J. Phys.*, 16, 24; 1962) added a high conductivity substrate. A few years later, Linsky (*Icarus*, 5, 606; 1966) suggested that the thermal conductivity in the upper few centimetres may be significantly temperature dependent.

So how do these older, pre-Apollo conclusions compare with those based on newer, more comprehensive measurements *in situ*? Keihm *et al.* (*Earth planet. Sci. Lett.*, 19, 337; 1973) have now combined *in situ* measurements of lunar surface brightness temperatures at the Apollo 15 Hadley Rille landing site, data from five thermocouples lying on or just above the surface at the same site and a density profile and a heat

Apollo data, to produce a model of the upper few tens of centimetres of the lunar regolith having the following characteristics.

The upper layer of the surface is about 2 cm thick and is strongly insulating, having a mean thermal conductivity in the range $0.9\text{--}1.6 \times 10^{-5} \text{ W cm}^{-1} \text{ K}^{-1}$ (*sic*). Below this surface layer there is a large conductivity gradient, resulting in a mean conductivity of $5.5 \times 10^{-5} \text{ W cm}^{-1} \text{ K}^{-1}$ at 5 cm depth; but at greater depths the conductivity increases more gradually to $1.4 \times 10^{-4} \text{ W cm}^{-1} \text{ K}^{-1}$ at 49 cm. In the upper few centimetres the conductivity is also strongly temperature dependent, and about 70% of the heat transfer at the highest temperatures is by radiation between particles.

The temperature dependent conductivity close to the surface is required to explain an observed high temperature gradient (an increase of 47 K in the upper 83 cm) and indicates the presence of very loosely packed material in the upper few centimetres. Since the particle configuration and degree of compaction in such material will be difficult to maintain once the material is moved, Keihm and his colleagues conclude that measurements made on returned lunar samples may indicate properties significantly different from those of the undisturbed lunar surface. This may be why their ratio of radiative to conductive heat transfer (at 350 K), for example, is almost twice that measured

Submillimetre Astronomy

M. SIMON

Department of Earth and Space Science, State University of New York at Stony Brook, Stony Brook, New York 11790

Although astronomy at submillimetre wavelengths is still in its infancy, work in two different areas—observations of HII regions and molecular clouds, and observations of the temperature minimum in the solar atmosphere—is particularly advanced.

NEARLY two decades of the electromagnetic spectrum from 20 μm to 1 mm have been virtually inaccessible to the astronomer because of severe absorption by the Earth's atmosphere. This spectral region is of great interest, however, from observations of the 3 K background radiation on the cosmological scale, to observations of star formation on the galactic scale, and the atmospheres of the Sun and planets locally. Recently, the submillimetre region has begun to be explored using balloons, rockets and aircraft as observing platforms, and from ground-based observatories through several atmospheric windows. Although these windows are poor compared to the optical and near infrared windows, they are usable at observatories where the atmosphere is particularly dry. This article is a discussion of the present status of submillimetre work but I shall not discuss observations of the 3 K background radiation or of the planets, as these have been reviewed recently^{1,2}.

Transmission of the Earth's Atmosphere

Figure 1 shows the transmission of the Earth's atmosphere in the infrared and submillimetre regions based on refs 3–5 and our own experience. The principal source of absorption in the far infrared is water vapour, and the figure is an approximate representation of the transmission under conditions of 1 mm of precipitable water vapour. It is clear that the atmosphere is opaque in the 100 μm region so that astronomical observations have to be carried out from aircraft flying at the top of the troposphere, or from balloons and rockets at yet higher altitudes. There are rather poor atmospheric windows in the 30 μm region, and again at 350 μm and longer wavelengths. These are usable for astronomical observations at sufficiently dry observatory sites. Several groups have begun to observe in these windows.

Under good conditions, the atmospheric transmission in the windows at 350 μm , 450 μm , and 650 μm is sufficiently stable to be represented by the exponential extinction law $\exp(-\alpha(\lambda) l \rho)$, where $\alpha(\lambda)$ is the intrinsic extinction coefficient, l the air mass in the line of sight, and ρ the precipitable water vapour. As it is notoriously difficult to estimate the atmospheric precipitable water vapour content, especially in night observations, I hesitate to quote absolute transmissions in these windows as a function of precipitable water vapour. The transmission at 350 μm is 30% for approximately 1 mm of precipitable water vapour in the line of sight (the uncertainty is in the calibration of the spectral hygrometer). Our measurements of the relative transmissions

$\alpha(350 \mu\text{m}) = (2.2 \pm 0.1) \alpha(1,000 \mu\text{m})$. From limited data from the few occasions when submillimetre observations, and 20 μm observations by the University of Hawaii group, were carried out simultaneously at Mauna Kea observatory, we estimate that $\alpha(350 \mu\text{m}) = (4 \pm 0.5) \alpha(20 \mu\text{m})$.

Galactic Sources

Direct observations of the emission of the coldest regions of our Galaxy must be made in the far infrared. Far infrared emission has been detected from HII regions and from regions of molecular emission at microwave frequencies. These observations are valuable for determining the total energy budget of these regions and the temperature and density of the interstellar dust in them. So far most observations have been in the 100 μm region from airborne platforms. Recently many of the same sources (as well as new sources) have also been observed at 350 μm and 1 mm. The telescope aperture in the ground-based observations is generally much larger than that available to the airborne work, so the observations at 350 μm and 1 mm have the advantage of much higher diffraction-limited spatial resolution. The sources are characterised by prodigious fluxes in the far infrared: for example, the 100 μm survey of 750 square degrees principally along the galactic plane carried out to a limiting sensitivity of $10^{-22} \text{ W m}^{-2} \text{ Hz}^{-1}$ yielded seventy-two sources. Of these, forty-six are clearly identified with HII regions (which in many cases contain radio molecular sources). Significantly, only one source discovered in the survey is possibly associated with a stellar object. Far infrared astronomy of galactic objects is thus distinctly the astronomy of extended objects. There is strong evidence that the emission of these objects is continuum emission since observations at 100 μm of a

Fig. 1 Transmission of the Earth's atmosphere at infrared and submillimetre wavelengths. The transmission is intended to be roughly representative of conditions of 1 mm precipitable water

Fig. 2 The spectra of the total radio free-free continuum flux density of Ori A, and the total submillimetre flux density from the Kleinmann-Low infrared nebula. As discussed in the text, the positions of the strongest emission from Ori A and the infrared nebula are separated by about 1 arc min. The submillimetre data are discussed in the text, and the radio data are from refs 43 and 44.

given source (for example, the well studied sources in Orion and the galactic centre regions) by different observers with similar beamwidths but differing spectral bandpasses yield similar flux densities⁷⁻¹². As dust is present in HII regions, and as many of the far infrared sources are also molecular sources (the dust is implicated as the catalytic agent in molecule formation), the most reasonable assumption is that the far infrared emission from these sources is the thermal emission of the dust grains. As I shall discuss later, the 20 μm , 100 μm , 350 μm and 1 mm data from the Orion far infrared source fit a thermal emission model quite well.

The mechanism of the heating of the dust is still poorly understood. The two possibilities considered involve very different assumptions about the nature of the far infrared sources. In the first, the emission is presumed to originate in a dusty Stromgren sphere^{8,11,13}, so that the HII region, as delineated by its Lyman continuum, and the far infrared source should be spatially coincident. In this model the heating of the grains is due to Lyman α radiation of the gas and direct radiation from the exciting stars. Supporting this view, Harper and Low⁸ in their original observations of HII regions in a 40 to 750 μm pass band found a rough proportionality between the observed far infrared flux and the free-free continuum flux density at 2 cm. Similar correlations have been found by the other groups^{11,14} observing HII regions at 100 μm . But all observers find that the Lyman α energy available (as estimated from the excitation of the HII region) is less than the energy required to account for the far infrared flux by about an order of magnitude. Johnson¹⁵ has shown that the total stellar luminosity and the far infrared are about equal in a number of HII regions. In the HII region M42 (in Orion), however, the exciting stars are separated by at least 1 arc min from the far infrared source so that it is not clear that the far infrared luminosity can be attributed to the energy input of the observed stars.

The other point of view is that the far infrared emission is not from dust in the HII region itself, but rather from dust in the dense molecular clouds that are associated with it¹⁵ (a detailed model of the possible association of the molecular cloud in Orion with the rest of the HII region is given in ref. 46 by B. Zuckerman). In this view, the heating of the dust grains could be caused by stellar or proto-stellar objects embedded in the cloud¹⁶. Ground based observations have

and unpublished work of D. Y. Gezari, R. R. Joyce, G. Righini and M. Simon) and DR21 (Rieke *et al.*⁴⁷) peaks at the position of the strongest molecular spectral line emission rather than at the peak of the radio free-free continuum. In Orion this emission is at the position of the strong 20 μm extended source discovered by Kleinmann and Low¹⁸, and in DR21 at the position of the OH source. The 1 mm emission from these sources also peaks at the positions (ref. 48 and private communication from P. A. R. Ade and J. D. G. Rather). Similarly, Emerson *et al.*¹¹ found that in several instances the peak of 100 μm emission from HII regions is displaced from the radio continuum peak.

Further high resolution observations in the far infrared are required to find the relative importance of these two contributions to the far infrared emission of HII regions, and very likely both processes will turn out to be important. For example, in an HII region such as M17, which does not (as far as is known) contain a very dense molecular source, and in which the strong 10 μm emission is coincident with the strongest radio-free emission¹⁹, the far infrared emission may well arise entirely from dust grains heated by ultraviolet radiation. Orion appears to have both kinds of sources. The Ney-Allen source²⁰, which peaks in the near infrared (this source is approximately centred on the Trapezium stars which are believed to be the exciting stars for the M42 nebula), can be accounted for naturally by emission from ultraviolet-heated dust. The second type of source is the Kleinmann-Low/molecular source which, as we have seen, gives rise to the far infrared emission. Finally, there are far infrared sources associated with dark clouds⁷ from which no radio free-free emission is known.

The two far infrared sources studied in greatest detail are the Kleinmann-Low/molecular source in Orion, and the complex of sources near the galactic centre. Figure 2 shows the spectrum of the total flux density of the KL source; as the source is extended, the plotted points are those believed to include the bulk of the flux from the source. The 20 μm total flux density is from Low²¹, the 100 μm flux density is from Hoffmann, Frederick and Emery⁷ and was obtained with a beam of 6 arc min, the 350 μm spectral point was obtained by Gezari *et al.* (unpublished) with a beam of 3.5 arc min, and the 1 mm flux density is the total obtained by Ade and Rather (private communication) by mapping over an area of 4 arc min diameter. The 100 μm , 350 μm , and 1 mm points, of course, include both contributions from the Ney-Allen source and from the free-free continuum radio source. The former is quite negligible relative to the KL source at submillimetre wavelengths. The free-free contribution is certainly negligible at 100 μm and 350 μm , but it makes a significant contribution at 1 mm as indicated by the extrapolation of the radio-free emission in Fig. 2. Kleinmann and Low found that the observed flux density and size at 22 μm could be fitted by an optically thick thermal distribution ~ 70 K (ref. 18). The spectrum in Fig. 3 supports this interpretation. As the observed flux density decrease at wavelengths longer than 100 μm is steeper than the ν^2 dependence given by the Rayleigh-Jeans Law, the source must be optically thin with a frequency-dependent optical depth at these wavelengths. It may be shown (ref. 15 and unpublished work of Gezari *et al.*) from general considerations based on the Kramers-Kronig dispersion law that $\tau(\nu) \propto \nu^2$ in the long wavelength limit. Calculations of the optical depth of silicates²², based on measurements of the optical constants of silicates in the lunar soil²³, fit this low frequency behaviour well. Thus, in the low frequency limit, the flux density from an optically thin isothermal dust cloud may be expected to have a ν^4 dependence. (A temperature distribution within the cloud could make the frequency dependence less steep.) The submillimetre data in Fig. 2 at wavelengths longer than 100 μm fit this model well (when correction for the free-free contribution to the 1 mm flux density is made). The frequency-

the temperature of the source. Detailed analysis of this data shows (unpublished work of Gezari *et al.*) that the temperature is probably from 60 to 74 K, in agreement with the results of Kleinmann and Low, that the source is becoming optically thin at $100\ \mu\text{m}$ and that $\tau(100\ \mu\text{m})$ must be between 0.2 and 5. As the observations from which these conclusions are drawn represent fluxes from the entire source, the values of the parameters quoted here must be regarded as averages over the source. There is no difficulty in accounting for the high optical depths at submillimetre wavelengths. The molecular radio observations show that the molecular hydrogen density might exceed $10^7\ \text{cm}^{-3}$ in the core of the molecular source²⁴. Using typical values for the grain absorption efficiency for silicates, a normal gas-to-dust ratio, and grain mass density of $1\ \text{g cm}^{-3}$, one then naturally obtains values of $\tau(100\ \mu\text{m})$ of order 1 through the molecular cloud. Integrating the submillimetre spectrum in Fig. 2 and taking 500 pc for the distance to the Orion nebula, the total luminosity of the KL nebula/molecular source is $4.8 \times 10^{38}\ \text{erg s}^{-1}$. As noted by Hartmann¹⁶, this luminosity is several orders of magnitude greater than could be reasonably accounted for by the gravitational collapse of the cloud, and the most probable source of heating the cloud is the radiation of one or several early type stars.

A tentative general conclusion from this analysis of the radiation from the KL nebula/molecular source is that molecular sources known to be very dense (that is, sources in which transitions of molecules requiring high molecular hydrogen densities for collisional excitation are observed) may be expected to have high enough optical depths at submillimetre wavelengths to be strong submillimetre sources. This is indeed the case in W49, W51, DR21(OH), and Sgr B2 which have been detected from $100\ \mu\text{m}$ to 1 mm (refs 7, 8, 15 and 47, and private communications from Ade and Rafter and from M. W. Werner and P. M. Harvey).

The strongest far infrared source known, after the Sun and the Moon, is the complex region of the galactic centre. Its spatial extent, as revealed by the airborne $100\ \mu\text{m}$ observations, is $1^\circ \times 2^\circ$. Hoffmann, Frederick, and Emery²⁵ mapped this remarkable region at $100\ \mu\text{m}$ (Fig. 3) and found excellent agreement between the regions of far infrared emission and 2 cm radio emission, which is again free-free emission, except for the nonthermal source Sgr A. The peaks in their map also coincide with the known molecular clouds in this region. One of these, Sgr B2, is the richest source of molecular emission known²⁶, and has also been studied at $350\ \mu\text{m}$ (refs 14, 47 and unpublished work of Gezari *et al.*). The molecular source is quite large and probably has a dense core. The core is apparently smaller than 5 arc min and is probably about 1 arc min in size^{27,28} (at the distance of Sgr B2 this corresponds to ~ 3 pc).

The great spatial extent of this source makes comparison of different flux measurements (even at the same wavelengths) difficult for two reasons. First, the observed flux clearly depends very strongly on the beamwidth so the beam pattern must be known accurately in order to deduce the source brightness. Second, all the observations use some type of sky chopping scheme where the source signal is differenced against a position on the sky some distance away (usually small for technical reasons). This observing technique measures the derivative of the source brightness distribution. Clearly, chopping arrangements with large beam spacing (or, ideally, an absolute temperature reference as used in the rocket infrared observations¹³) are to be preferred. The present $350\ \mu\text{m}$ observations illustrate the difficulties of comparison of observations with different instrumentation. Observations of Sgr B2 with a 1 arc min beam and beam spacing of 4 arc min show a source of half power width ~ 3 arc min (N-S) $\times \sim 2$ arc min (E-W) and a peak flux density of about 8,000 flux units (Rieke *et al.*⁴⁷). On the other hand, observations of the same area with a 3.5 arc min beam

Fig. 3 Contour map of the galactic centre region at $100\ \mu\text{m}$ reproduced from ref. 25. The source Sgr B2 discussed in the text is within the northernmost of the three strong sources. (Reproduced with permission from *The Astrophysical Journal*, University of Chicago Press.)

$\sim 50,000$ f.u. and an extent 5 to 10 arc min E-W and about 10 arc min N-S (ref. 15 and unpublished work of Gezari *et al.*). These latter observations are in rough agreement with the structure in the $100\ \mu\text{m}$ map in Fig. 3. The two sets of $350\ \mu\text{m}$ observations are reconcilable and should be taken to be complementary. Thus the relatively small component is probably the dense core of the molecular source discussed already, and is seen superimposed on the more extended source.

Finally, it is interesting that the far infrared sources discussed so far have very little emission outside the $20\ \mu\text{m}$ to 1 mm band. At low frequencies, the approximately ν^4 flux density decrease makes detection difficult at radio wavelengths. For example, scaling the $350\ \mu\text{m}$ flux density of Orion to 3.5 mm suggests that the thermal emission from the dust in the molecular cloud should contribute only ~ 2 f.u. in a 3.5 arc min beam at 3.5 mm. Such a small contribution may be difficult to disentangle ambiguously from the very strong contribution due to the free-free emission. In a 3.5 mm survey of many far infrared sources, including Orion, Brown and Broderick²⁹ were unable to detect such an excess flux. It seems likely, however, that the upturn at 3.5 mm in the radio spectrum of the remarkable source Sgr B2 observed by Hobbs *et al.*³⁰ is from the tail of the far infrared emission. On the other hand, these sources are difficult to observe at wavelengths shorter than $20\ \mu\text{m}$ since their temperatures are so low. But submillimetre astronomy of galactic sources is still young, and the present results suggest that further observations will provide a valuable probe of the physical conditions in the cold components of the interstellar medium.

Solar Atmosphere

The radial temperature distribution of the solar atmosphere has a minimum between the photosphere and the corona in a region spanning nearly 500 km which is exceedingly difficult to study. Here I discuss the role of submillimetre observations in defining a model for the physical parameters in this region, their implications for the region's structure, and the potential contribution of these observa-

Fig. 4 The brightness temperature at the centre of the solar disk as a function of wavelength as given by the HSRA model³⁶. The data points are those published since the publication of the HSRA and are from ref. 6 (○) and ref. 37 (●).

The continuum radiation from the temperature minimum is assessable only in the rocket ultraviolet, or in the submillimetre region of the spectrum. The submillimetre continuum is perhaps more directly tractable since the source of opacity (free-free absorption due to the H^- ion) is well understood, and no strong emission features, unlike in the ultraviolet, are expected. Submillimetre observations of the solar brightness temperature as a function of wavelength at the centre of the disk may thus be inverted into the distribution of the temperature in the solar atmosphere as a function of optical depth. Submillimetre observations have already played an important role in this respect. Airborne observations in the 50 to 300 μm regions³¹⁻³³ and recent rocket observations³⁴ have indicated that the temperature minimum is 4,300 K rather than 4,600 K as had been previously inferred. This revision alleviates difficulties in understanding the 4,300 K temperature at the core of the Ca K line³⁵ and has been incorporated in the HSRA model of the atmosphere³⁶. Fig. 4 shows the temperature profile as a function of wavelength given by the HSRA model at submillimetre wavelengths. As the HSRA was adjusted to fit the best data available at the time, I show in Fig. 4 only measurements^{6,37} obtained subsequent to the publication of the HSRA. (Comparison of the HSRA with the data available at the time of its publication is in Fig. 2 of ref. 36.) The agreement of recent data with the HSRA is quite satisfactory. The strong upturn at $\lambda > 500 \mu\text{m}$ is dictated by the high brightness temperatures measured at 1 mm and longer wavelengths. There are no observations available of the brightness temperature between 500 μm and 1 mm, representing a factor of four in the optical depth, so data are needed to delineate the temperature distribution in this region.

Further information on the temperature distribution and structure of this region may be derived from the brightness temperature variation across the disk. For example, if the solar atmosphere is homogenous and spherically symmetric, the brightness temperature distribution should be entirely determined by the variation of central brightness temperature with wavelength, and the parameter $\lambda^2/\sqrt{1-r^2}$, where r is the fractional distance to the limb from the centre of the disk. In the HSRA model the temperature minimum occurs at about 200 μm . Limb darkening should be observed at longer wavelengths; the HSRA model predicts $\sim 5\%$ limb brightening at 350 μm at $r=0.8$. Our scanning observations at 350 μm appear to rule out this degree of limb brightening. Limb darkening at 1 mm has been reported^{38,39}, but recent observations at 1 mm, in which a detailed analysis of the beam pattern was made, seem to be consistent with no limb

P. E. Clegg). Departures from the limb brightening predicted by a homogenous model with the HSRA temperature profile may be interpreted in terms of either a revision of the temperature gradient in the HSRA, or a dropping of the homogeneity assumption. In view of the good agreement of the model with the brightness temperature measurements at the centre of the disk, and the well-known inhomogeneity of the solar atmosphere both above and below the region of the minimum, it is likely that here too the homogeneity assumption will have to be relaxed.

High resolution mapping observations at these wavelengths may also be expected to improve understanding of the electron density and temperature of active regions. Ade *et al.*⁴⁰ have mapped one active region at effective wavelengths 400 μm , 800 μm , and 1,200 μm , and found that the brightness temperature increased from 200 K at 400 μm to 350 K at 1,200 μm . These submillimetre observations may indicate the existence of a dense core of the active region that is nearly optically thick at these wavelengths. Further observations of active regions, and detailed comparison with radio observations, are clearly required.

Future Prospects

Submillimetre observations of extragalactic objects are still sparse, although the observations so far show it to be an area of great promise. NGC1275, M82 and 3C273 have been detected at 1 mm (unpublished work of Ade and Rather), NGC253 (Rieke *et al.*⁴¹) and possibly M82 (ref. 41) at 350 μm (although the flux calibration for M82 is almost certainly in error), and M82 and NGC253 at 100 μm (ref. 42). The millimetre wavelength radiation of sources such as 3C273 and NGC1275 is known to be non-thermal, and at least part of the flux is time-varying and believed to originate in rapidly-evolving small components. Observations of variability at submillimetre wavelengths would place severe restrictions on the models of these components. It is premature to speculate on the nature of the submillimetre radiation of objects such as NGC253 (which is the strongest extragalactic source at 10 μm) and M82, but the radiation may well be thermal.

Technically there are several promising areas. Fainter objects will become observable through the use of larger apertures and stabilised observing platforms in the airborne work, and the development of more sensitive detectors for both the ground-based work and airborne work (because in both the limiting noise at present is detector noise). This discussion of submillimetre astronomy is based on data obtained by broad-band photometry or very coarse resolution Michelson interferometry. There is a great incentive to develop submillimetre spectral line systems to observe fine structure lines, recombination lines, and molecular lines that are accessible in this region of the spectrum and to use them as astrophysical probes. Several active developmental programmes are under way, and it is probably not too optimistic to believe that in a few years the time will be right for a similar preliminary review of submillimetre line astronomy.

I thank P. Ade, P. M. Harvey, D. Morrison, J. Rather, G. Rieke, and M. Werner for communicating results in advance of publication, and D. Gezari, R. Joyce, and G. Righini, who are making crucial contributions to the submillimetre programme at Stony Brook, for comments. Most of our observational work was done at Mauna Kea Observatory of the University of Hawaii and we thank the director and staff for grants of observing time, assistance, and hospitality. We also thank the State of New York and National Science Foundation for support.

Conditions Limiting Multiplication of Fibroblastic and Epithelial Cells in Dense Cultures

R. DULBECCO* & J. ELKINGTON

Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2

The multiplication of epithelial cells in plastic dishes is limited by the amount of plastic surface available per cell, that of fibroblastic cells by the availability of medium factors. Contacts between cells do not appear to limit the multiplication of either cell type. The multiplication of fibroblastic cells is even favoured by shorter intercellular distances, suggesting a distance-dependent helper effect between cells.

CULTURES of untransformed cells growing on a glass or plastic surface display the phenomenon of "density-dependent growth inhibition": under standard conditions of

cultivation cell multiplication stops when a certain cell density, characteristic for each cell type, is reached. If a strip of cells is removed from a stationary culture, cells migrating from the borders into the denuded area (the wound) are activated to multiply, although the medium remains unchanged¹. It has been shown that the activation occurs when the cells leave the dense layer². The differential ability of the cells in the wound to initiate DNA synthesis in comparison to those in the layer has been defined as topoinhibition³. Although topoinhibition is a useful parameter for characterising cell lines, especially in relation to transformation, its mechanism is undefined. The basic dilemma is whether the multiplication of cells in the layer is inhibited by the intimate contacts between cells ("contact inhibition of growth") or by a lower ability to utilise components of the medium, especially serum⁴. The reason for the uncertainty is that most experimental procedures affect many variables at once.

* R. Dulbecco is also a fellow of The Salk Institute, La Jolla, California.

Fig. 1 Final number of Balb/c 3T3 cells in cultures of different size. Approximate dish diameters in centimetres are shown on the abscissa. *a* to *d*: Single supply of medium with the following concentration of calf serum: $\blacktriangle$, 20%; $\triangle$, 10%; $\circ$, 5%; $\bullet$, 2%. *e*, *f*: Daily change of medium with 10% serum. The number of cells in the inoculum of each set is indicated by the heavy horizontal line. The lines connecting cell numbers for different size dishes and the same concentration of serum terminate at the inoculum level when the next point is below that level, that is, there was loss of cells. Loss of cells at all three dish sizes for a certain concentration of serum is indicated by placing the symbol for that serum concentration below the inoculum line.

Varying Dish Size

The experiments we are now reporting are aimed at clarifying the role of cell-to-cell contacts under conditions in which the availability of medium is constant. To this end we have studied the effect of a single variable, the amount of dish surface available to each cell, on the number of cells present per dish at saturation, using the following scheme. Parallel cultures were prepared, each with the same number of identical trypsinised cells and in the same volume (6 ml) of medium (reinforced Eagle's containing calf serum at the indicated proportions), but in dishes (plastic, Nunc) of different sizes: 30, 50 and 90 mm in diameter. Hence the dish size was the principal variable. In the 30 mm dishes the depth of medium was about 7 mm, about 1 mm in the 90 mm dishes. The plastic area available to each cell in the 30 mm dishes was, on the average, about one-eighth that in the 90 mm dishes. The cultures were maintained in a CO_2 -flushed, high humidity incubator and were allowed to grow without medium changes until growth stopped, as shown by the absence of mitoses. The validity of this criterion was confirmed in some cases by growth curves. Usually, growth stopped somewhat sooner in the 30 mm dishes: 4 to 7 d, depending on initial cell density, compared with 5 to 10 d in the 90 mm dishes. After growth stopped, the cells were detached with trypsin and counted in a Coulter counter. Several cell lines were used: Balb/c 3T3 (ref. 6) and BHK 21 (Cl 13) (ref. 7), fibroblastic; CV-1 (ref. 8), and BSC-1 (ref. 9), epithelial; and SV3T3 (ref. 10) and Py BHK (produced in this laboratory), transformed. In different experiments the inoculum varied between 10^4 and 10^6 cells per dish, and the serum concentration in the medium between 2% and 20%.

In this protocol the main variable is the distance between cells, which in turn affects the extent of contact between them, their ability to move and to stretch. Two other variables, the depth of medium and possibly the nature of the plastic employed in the manufacture of dishes of different sizes, seem to be of little importance on the basis of internal controls, as indicated below.

The experiment has three possible outcomes. If the area of the plastic surface available to a cell limits cell multiplication, the final number of cells in a dish should be proportional to the surface of the dish. If, on the other hand, growth is limited by medium components, the final cell density should be equal on all size dishes. Finally, if there is a distance-dependent helper effect between cells (for instance, if growth is helped by cell-to-cell contacts or by labile substances produced by the cells), the number of cells should be inversely related to the dish surface.

The results with Balb/c 3T3 cells, which are characterised by a high topoinhibition and high serum requirement⁶, are given in Fig. 1*a* to *d*. When the cell inoculum and the serum concentration were high, the dependence of final cell number on dish size was that expected from limitation by medium. When the cell inoculum and the serum concentration were small, the relation conformed to that expected from a distance-dependent helper effect.

The latter result might also have been produced by loss of medium components to the walls of the dish, which would be more pronounced in the larger dishes. This possibility was tested by incubating the medium in the dishes for 3 d and then adding cells to it (5×10^5 per dish). The final number of cells per dish was about half that of similar cultures whose medium had not been preincubated, irrespective of dish size. Thus there is no evidence for loss of medium to the plastic, but only for partial inactivation. Conceivably, the effect may be due to loss to the walls of some growth factor present in the cell inoculum; but this possibility was not tested. Under no circumstance was there evidence that the available dish surface was limiting the growth of these cells.

The distance-dependent helper effect affects the growth rate of the cells, which is slower in the larger dishes (since they produce fewer cells in a longer time). The lower final cell number on the larger dishes may be due to greater inactivation of medium components, since a longer time is required to reach saturation.

We tested whether a dish surface requirement for Balb/c 3T3 cells became demonstrable when the availability of medium was increased by growing cultures with daily changes of 10% serum medium. As shown in Fig. 1*e* and *f*, these cells reached a resting stage with a larger number of cells per culture; but although the relation of final cell number to dish size showed some dependence on available surface, limitation of medium was still the most important factor stopping growth.

These experiments were repeated several times with similar results: similar results were also obtained with BHK cells.

Some other results of these experiments should be noted. In the first place, cultures with the same serum concentration and similar initial density of inoculum cells (and therefore similar helper effect) tended to yield similar (within a factor of two) final cell numbers irrespective of dish size (compare for instance points *d*9 with *b*3 and *b*9 with *a*3 in Fig. 1). This shows that the depth of the medium and the nature of the plastic have a minor importance for the final number of the cells. In the second place, when the ratio of cells to serum in the inoculum was small the final cell number was lower than the inoculum, indicating loss of cells. This result suggests that cell survival depends on a stoichiometric relationship between serum and cells. A stoichiometric relationship also holds between amount of serum and number of new cells produced, 0.06 ml serum corresponding to about 5×10^6 Balb/c 3T3 cells. This relationship

shows that the access of medium components to the cells is not affected by the degree of cell overlaps.

The epithelial cells of the BSC-1 and CV-1 lines, which have a high topoinhibition but a low serum requirement⁴, gave different results (Fig. 2). In all cases growth was limited primarily by the restriction of dish surface, especially when 10% serum was used. There was also, however, some medium limitation or helper effect because the cell numbers on 90 mm dishes were at most five times those on 30 mm dishes, although the dish surfaces differed by a factor of eight.

Fig. 2 Same as for Fig. 1, except for the last set, which had daily change of medium with 10% calf serum, there was a single supply of medium in all cases. For symbols referring to serum concentration see Fig. 1.

For transformed SV3T3 cells which have very low topoinhibition and serum requirements⁴ (Fig. 2) there was little effect of either the amount of serum or dish size in the range used. A similar result was obtained with Py BHK cells. With SV3T3 cells, changing the medium daily increased the final cell number to a constant value irrespective of dish size. Hence there is no evidence that these cells have a dish surface requirement even when medium is plentiful. It should be noted, however, that transformed cells did not attain a stationary stage: growth was stopped by the spontaneous detachment of the cells from the plastic.

Growing and Stationary Cultures

The result that under standard culture conditions multiplication of Balb/c 3T3 or BHK cells is not stopped by restriction of available dish surface shows that their growth is not limited by contacts between cells or by their inability to move or to stretch. Before this conclusion was used to explain the results of wound experiments, we examined the possible role of a difference in the two experiments. The present experiments study the effects of cell crowding on growing cultures, whereas the wound experiments employ already crowded and stationary cultures. The role of this difference was tested by varying the experimental procedure: Balb/c 3T3 cells were seeded in exhausted medium (origin-

resting cultures of the same cell type and diluted with the addition of fresh medium without serum (half the volume). The cells did not grow but formed stationary cultures. Then serum was added to a concentration of 10% to start growth. The results obtained were similar to those obtained by the standard procedure.

Fibroblastic and Epithelial Cells

These experiments suggest that cell multiplication is limited by different mechanisms in fibroblastic and epithelial cell cultures and, accordingly, that the significance of the wound experiment and of topoinhibition are also different.

With fibroblastic cells, a restriction of the available surface to which they adhere only begins to limit growth at extraordinarily high cell densities. Under usual culture conditions their multiplication is stopped by the exhaustion of medium components, especially serum. Therefore, activation of fibroblastic cells that migrate from a dense layer into a wound is likely to be caused by their ability to utilise the medium more efficiently. Indeed, Stoker¹¹ has shown that there are important differences in the state of cells in a layer and of isolated cells as are found in a wound, in that isolated cells have better access to the medium. Probably the limitations in the layer are not affected by its density within a broad range.

In contrast, with epithelial cells a dish surface restriction is the predominant factor stopping growth; hence the increased availability of dish surface to the marginal cells after wounding may contribute to activate their growth. However, even for these cells it is unlikely that the dish surface requirement has to do with an inhibitory effect of contacts between cells. In fact, the epithelial cultures become resting long after the cells start touching each other; and when the cultures are wounded the cells at the edge of the wound do not become free from each other (except, perhaps, transiently during wounding) but migrate as a sheet, at the same time expanding their surface¹².

Topoinhibition seems to result from different mechanisms in fibroblastic and epithelial cells; lower utilisation of medium components by cells in a layer in the former case, and a dish surface requirement (also perhaps with a decreased medium utilisation in the layer) in the latter case. The dish surface requirement may be an attribute of cells that must form a monolayer, as many epithelial cells do in nature in relation to their basal membrane. Fibroblastic cells need not form a monolayer either in nature or in cultures.

On the basis of the foregoing, we believe that there is no experimental support for the concept that "contact inhibition of growth" is responsible for cessation of growth in dense cultures.

Role of Diffusion Boundary Layer in Contact Inhibition of Growth

M. G. P. STOKER

Imperial Cancer Research Fund Laboratories, Lincoln's Inn Fields, London WC2

Use of a miniature pump to produce a local increase in velocity of medium across the surface of confluent 3T3 cells stimulates growth which is limited to the region of high velocity. This indicates that growth is limited by a diffusion boundary layer close to the cell surface. The events at the edge of wounded cell layers (topoinhibition) can be explained by local variation in the fluid microenvironment rather than by alterations in contact between cells.

CONTACT inhibition of growth of cultured fibroblasts like contact inhibition of movement¹ has attracted much interest but the role of contact is still uncertain, and for this reason the alternative names density-dependent inhibition² and topoinhibition³ have been proposed. It is now acknowledged that the supply of medium⁴ and particularly serum⁵⁻⁷ plays an important part in this phenomenon. Nevertheless, it has been difficult on this basis alone to explain the very short-range topographical effects seen in wounded cultures, which have remained the strongest evidence that contact between adjacent cells plays a role in inhibition of growth in confluent cell layers.

When a strip of 3T3 cells is mechanically removed from a confluent non-growing monolayer, growth begins in those cells which migrate from the edge of the confluent sheet into the denuded area⁸, and in individual cells this can be correlated with loss of contact with neighbours⁹. Since the non-growing cells still in the confluent sheet and the growing cells in the wound are in the same medium only a few micrometers apart, it has seemed likely that the difference in growth is due to changes in the intimate relationship between cells, probably involving contact.

There is, however, an alternative explanation^{9,10}. This would suppose that the emigrating cells at the wound edge travel through and respond to a concentration gradient in the surrounding medium, affecting the availability of some substance critical for growth. At first sight it might appear that convective movement in the fluid should be sufficient to prevent the development of such a very localised gradient, but fluid movement is known to be reduced in the layer very close to the cell surface. A sufficient increase in the velocity of the fluid medium over a cell sheet might, however, perturb a local concentration gradient and alter the growth of the cells.

Riddle's Pump

For this purpose I have used a small pump developed from an agglutination chamber designed by Riddle¹¹ which

introduces a recirculating movement into the existing medium in the dish, in a narrow stream, 0.5 to 1 mm wide at velocities of up to about 100 mm s⁻¹. The pump (Fig. 1) consists of a glass capillary tube about 3 cm long and of 2 mm bore, narrowing to about 1 mm at the tip, which is lowered into the medium.

The other end of the tube is inserted directly or by a flexible connector tube into the opening in a hearing aid earpiece (Medresco OL575, Cosmocord Ltd, Waltham Cross, U.K.). The latter is attached to a variable transformer with an output of 2-3 V a.c. at 50 Hz. This causes oscillation in the medium in the capillary tube which is translated at the tip into a unidirectional outward flow. The jet of medium produced is a narrow stream which fans out about 5 mm from the tip of the capillary tube and then circulates slowly as shown in Fig. 1. It has not been possible to measure the velocity accurately with the current used, but it is more than 10 mm s⁻¹ in the centre of the stream with a theoretical maximum of 100 mm s⁻¹ calculated from the oscillatory excursion in the capillary tube. Close to the surface of the cell layer this is reduced to 2-4 mm s⁻¹. Away from the main stream, in the recirculation region, the velocity is reduced to 1-4 mm s⁻¹, and close to the cell layer in this region it is too slow to measure.

Fig. 1 Pattern of medium recirculation produced by pump across edge of cell sheet. Relative velocity indicated by length of arrows.

Cultures of Balb 3T3 cells were grown to confluence in Dulbecco's modification of Eagle's medium with 10% foetal calf serum, and left without medium change for 4-7 d before use. The stationary sheets were wounded with a razor¹² and in most experiments fresh medium was added with 5% serum which is sufficient to stimulate growth in about 10% of cells in a confluent layer. The pump was directed across the edge of the wound towards the cell sheet with the tip of the denuded area about 2 mm from the edge of the cell layer and was allowed to run continuously while cultures were incubated in containers flushed with 10% CO₂. Controls were set up under identical conditions but with no pump.

Effect of Increased Velocity of Medium

When the cultures were examined after 26 h the number of mitoses and total cell numbers per unit area were seen to be increased in a small region of the cell sheet exposed to the fastest stream from the pump (Figs 2 and 3). A few millimetres from the main stream, even in the recirculating region the numbers of cells and mitoses were similar to those found in the rest of the dish and in the control unpumped culture. The mitotic index, which allows for the variation in cell numbers, was highest in the centre of the stream, 2.7% (19/700) compared to 0.5% (5/950) elsewhere in the dish.

Fig. 2 Effect of local change in velocity of medium on distribution of mitoses. A strip of cells from a confluent stationary culture of 3T3 cells was removed with a razor, fresh medium with 5% calf serum was added, and the cultures incubated with the pump operating for 26 h, directed across the edge of the sheet. Each dot represents a mitosis at the distance shown from the pump.

After 22 h exposure to ³H-thymidine and subsequent autoradiography the distribution of labelled nuclei in the confluent sheet was similar to that shown for mitoses in Fig. 2. 76% of cells were labelled in the region of the jet compared to 10% elsewhere (at least 200 counted). In contrast 81% of cells emigrating into the wound were labelled irrespective of relationship to the jet.

Since cell density was increased and mitotic cells were not removed by the jet it seemed unlikely that the stimulation of growth was due to local reduction in cell density and contact caused by detachment of cells. This was confirmed by time lapse cinematography of the area in the stream, which showed no loss of cells. The film also showed that there was no displacement or distortion of cells in the direction of the medium flow. A temporary increase in local cell movement compared to unpumped cultures was seen which lasted up to 16 h. Since the movement stopped between 16 and 22 h, it was not due to a direct physical effect of the fluid movement on the cells.

Fig. 3 Effect of local change in velocity of medium on cell numbers. Same culture as in Fig. 2. Cell numbers per unit area (0.15 square mm) are shown across the cell sheet parallel to the wound edge and at distances shown from the pump. Controls are (1) from the opposite side of the same layer (behind the pump) and (2) from a parallel but unpumped culture.

to be due to a direct physical effect of the fluid movement on the cells. It therefore seems likely that the stimulation of cell growth and movement with increase in velocity of the medium is due to concentration changes in the fluid micro-environment itself.

The Diffusion Boundary Layer

The behaviour of molecules in fluid close to a solid reactive surface has been extensively studied by physical chemists. Since the convective movement of most fluids approaches zero near a solid surface over which flow occurs, the transfer of molecules to and from the surface is largely limited to the relatively slow process of diffusion. This results in a diffusion boundary layer^{13,14} which can act as a barrier close to the reactive surface. If, for example, a cell rapidly removes a molecule essential for growth from the medium, the concentration near the cell surface will fall to a level determined by the uptake rate and the rate of replenishment by diffusion from the bulk of the medium. The supply of such a molecule may become limiting and the process (growth) then becomes diffusion controlled. The restriction can be relaxed by raising the concentration of the substance in the bulk medium, or alternatively by reducing the diffusion boundary layer. For a particular fluid the diffusion boundary layer is characteristic of each type of molecule and it is usually defined as the region with a concentration less than 90% of that in the bulk of the fluid¹³. Apart from the diffu-

Fig. 4 Effect of local change of medium velocity on uptake of stain. A confluent layer of 3T3 cells was fixed and exposed to Giemsa stain (0.03%) with the pump operating. After 3 min, uptake of stain was measured by microdensitometer tracings at right angles to the fluid flow and at distances shown from the pump.

sion coefficient and the net loss to the reactive surface, which cannot be varied, the diffusion boundary layer is inversely proportional to the square root of the velocity of the medium flowing over the surface. The velocity can be increased and, as shown here, this does affect cell growth.

Effect of Velocity on Staining

The existence of a diffusion boundary layer, even over a fixed cell layer, may be demonstrated by the effect of velocity on uptake of a stain such as Giemsa stain. Staining of a confluent sheet of 3T3 cells may barely be detected after 3 min exposure to dilute Giemsa stain (0.03%). Use of the pump, however, to produce a local increase in fluid velocity over the sheet causes uptake of stain limited to the region of high velocity. Figure 4 shows microdensitometer tracings across a cell sheet at right angles to the fluid flow and at varying distances from the jet (see Fig. 3). It shows the increased absorbance due to higher stain uptake limited to the narrow band exposed to the stream of medium. By coincidence this corresponds topographically and therefore in velocity to the region of growth stimulation produced by the pump in living cell sheets. It does not follow, however, that a molecule limiting for growth is of a similar size to the methylene blue eosin in Giemsa, since the uptake rate may be different.

Growth in Wounded Cell Sheets

This investigation was carried out to find out if concentration changes in the medium over a wound could account for growth of cells migrating over a very short distance from the edge (of the order of one cell diameter). Assuming negligible uptake of a critical substance by the supporting plastic, there will be no diffusion boundary layer and no reduction in concentration of medium constituents over the denuded area

up to the edge of the cell sheet (or a single cell). At the wound edge, however, diffusion can occur laterally as well as vertically, so the boundary does not start abruptly. It increases in proportion to the square root of the distance from the edge of the sheet. This has been studied by chemists in the dye industry¹⁵, and even in fixed 3T3 cells uptake of Giemsa stain may be increased at the edge of a cell sheet compared to the rest of the sheet. It means that the concentration of a critical substance at the surface will be higher near the edge of a wound and then fall rapidly over the undisturbed layer as the diffusion barrier increases.

Since the critical substances themselves and many of the parameters are unknown, the shape of the resulting concentration gradient over the edge cannot be determined. If, however, the diffusion boundary layer becomes maximal over a distance of one or more cell diameters it will not be fully developed over isolated migrating cells or the single row of cells lining the edge, and the concentration of a limiting substance over such cells will not fall to the same level as that over the continuous sheet. Consequently, with limiting nutritional conditions, the growth of confluent cells would be restricted, while isolated cells which had migrated a short distance into the denuded area would be able to grow (Fig. 5a). A sufficient increase in the velocity of the medium would reduce the boundary layer and increase the concentration over the sheet (Fig. 5b).

It should be noted that an increase in velocity in any direction, not necessarily over a wound edge, will reduce the diffusion boundary layer. This has been confirmed by placing the pump over the cell sheet where it still stimulates

Fig. 5 a, Diagram showing changes in concentration of a hypothetical limiting nutrient across edge of a wound. Top part shows section of cell layer across wound with migrating cell on right, in stationary medium (convection only). Middle part shows concentration distribution vertical to cell sheet (y axis) over different regions. Lower part shows concentration distribution at the cell surface horizontally across the wound edge (x axis). C_c —concentration of hypothetical substance limiting growth of cells migrating over wound edge.

growth. When the medium flows towards the sheet from a denuded region without uptake of critical nutrients, however, the effect of the increased velocity is enhanced.

This paper emphasises the role of the diffusion boundary layer in limiting the uptake of critical nutrients or growth factors from the medium. The barrier could, however, operate in the opposite way, by preventing the escape of inhibitory molecules released by the cells. On present evidence the two mechanisms cannot be distinguished.

The original suggestion that a diffusion barrier could account for many of the effects of cell density was based on experiments with opposed cell layers made by Rubin and Rein¹⁰. My data support this view and show that concentration changes in the microenvironment could account for the highly localised growth of 3T3 cells at the edge of wounds and presumably also at the circumferences of colonies¹⁶. On this basis the reduction in density-dependent inhibition of growth, or topoinhibition, by virus transformation can be explained by a lowering of nutritional requirements. Even in those variants which show a lowered requirement for serum growth factor while remaining sensitive to topoinhibition¹⁷, another essential nutrient may be limiting.

It may be concluded that topoinhibition, as manifest at wound edges in 3T3 cells, is no longer evidence that contact between cells regulates their growth. The accompanying paper¹⁸ reaches the same conclusion on different grounds.

I am grateful to Dr P. Riddle for help with the pump and for time-lapse cinematography, to Mr Denis Piggott for technical assistance, and to Dr N. Maroudas for discussion.

LETTERS TO NATURE

PHYSICAL SCIENCES

A Double Quasistellar Object

BECAUSE QSOs are rare^{1,2} the discovery of close pairs with discordant redshifts is improbable if they are randomly distributed on the plane of the sky. But Stockton³ has reported that Ton155 and Ton156 form a pair of 17 mag QSOs, with a separation of approximately 35 arc s. For QSOs randomly distributed on the plane of the sky he gives the probability for an accidental occurrence of this close pair as 6×10^{-8} .

Visually, 1548+115=4C11.50 (ref. 4) is another close pair of blue stellar objects. The brighter object (1548+115a) is approximately 17 mag, and is followed 4.8 arc s east and 0.4 arc s south by the 19 mag object 1548+115b. The pair was first noted by Hazard and Jauncey (see ref. 5) in a programme of 4C identifications, and has also been noted by Murdoch and Hazard (unpublished) in a programme of identifications based on Molonglo radio positions. It had been found earlier⁴ that 1548+115b was a QSO although its redshift had not been determined nor had the nature of 1548+115a been established. We report here that 1548+115a is also a QSO and give additional spectral information for both objects. In particular we note the very different redshifts of the objects; $z=0.4359$ for 1548+115a and $z=1.901$ for 1548+115b. The radio source is a 3C273 type double (Ekers and Fanaroff, private communication) with one component coincident with 1548+115a. There is a faint red wisp of otherwise unknown characteristics visible on the National Geographic Mount

On the nights of August 1, 3–6, and 24–25, 1973 (UT), 1548+115a,b were observed optically with the Cassegrain scanner⁶ of the 120-inch (305-cm) telescope. At that time of year 1548+115 can only be observed early in the evening in the western sky. The astronomical seeing was generally good during the earlier observing period and small (~ 2 arc s) spectrograph entrance apertures were used to reduce the background illumination from the lights of nearby cities. On the nights of August 24–25 the conditions were much poorer and only 1548+115a was observed. The use of small apertures, especially in the presence of substantial atmospheric dispersion, prevented us from obtaining an accurate continuum flux calibration. For this reason we are uncertain of the spectral index of the continuum although the magnitude estimates obtained in August ($m_v=16.8$ and 18.8) are in good agreement with those obtained earlier⁴. Our best estimate for the spectral index of 1548+115a is $\alpha=0.8 \pm 0.5$ and for 1548+115b $\alpha=0.6 \pm 0.4$ where α is the index in the equation $f_\nu \sim \nu^{-\alpha}$. Because the objects are so close together scattered light is a potential problem, but measurements of the scattered light from a bright star set 5 arc s off the slit showed no significant effects.

Both objects show rich emission line spectra. The observed lines, their identifications, and equivalent widths are listed in Table 1. The adopted redshift for 1548+115a is $z=0.4359$ and for 1548+115b we adopt $z=1.901$. If both objects were at the cosmological distance corresponding to $z=0.4359$ their separation would be about 40 kpc ($H_0=50 \text{ km s}^{-1} \text{ Mpc}^{-1}$, $q_0=1/2$). Figure 1 shows the observed spectra of the two objects. They seem to be normal for QSOs. Also the objects seemed stellar in the television guiding monitor of the 120-inch

Fig. 1 Spectra of 1548+115a,b. Evidence of poor subtraction of the strong Hg night sky lines at $\lambda\lambda 3650, 4047$ may be seen in the spectra. But a close inspection of our data shows that the strong absorption feature seen at $\lambda 4038$ in the spectrum of 1548+115b is not caused by incorrect subtraction of Hg $\lambda 4047$. The two vertical lines show the correspondence between the $\lambda 4038$ and $\lambda 4495$ features in the spectra of 1548+115a,b.

would be classified as a normal QSO. In addition to the close proximity of the two objects to each other in the plane of the sky and the possible alignment of the optical and radio sources, there are several coincidences in the spectra of the two objects.

First, there is a strong absorption feature at $\lambda 4038$ in the spectrum of 1548+115b that lies slightly to the red of the redshifted Mg II $\lambda 2800$ emission peak in the spectrum of 1548+115a. The spectral data are not of high enough quality to decide conclusively if the feature is due to Mg^+ or to some other ion, such as C^{3+} . An accurate determination of the profile of the absorption line is hindered by the presence of a strong night sky line, Hg $\lambda 4047$, in the red wing of the feature. But we were able to use the night sky line to determine the instrumental profile and to construct artificial profiles representing doublets with separations corresponding to C^{3+} and Mg^+ . A comparison of these profiles with the observed profile is given in Fig. 2.

Absorption	4038	—	12	—
C IV	4493	1549	83	1.901
C III*	5555	1909	65	1.910

Inspection shows that the absorption feature is probably due to C^{3+} .

Second, the presence of emission features close to $\lambda 4495$ in the spectra of both objects led to speculation that the C IV $\lambda_{\text{O}} 1549$ feature might be present in both objects at $z=1.901$. But the line of $\lambda 4496$ in the spectrum of 1548+115a is very probably a blend of the O III $\lambda 3122, \lambda 3133$ Bowen fluorescence lines⁷ in the $z=0.4359$ redshift system. The other lines in the O III cascade chain would be confused with the [Ne V] $\lambda 3346, \lambda 3426$ doublet and are possibly present at their expected strengths. Several other QSOs are known to have an emission line at a rest wavelength near $\lambda 3135$. Ly-α at $\lambda 3527$ does not appear in our spectrum of 1548+115a, a circumstance that strengthens the probability that the wavelength agreement between the $\lambda 4495$ features is accidental.

Finally, we note that the wavelength ratio $(1+z)_a/(1+z)_b = 2.02$. Although the observational data are sufficiently accurate to exclude the possibility that the true ratio as determined from the emission lines in the two objects is exactly 2, it would be possible for the departure from 2 to be caused by small peculiar motions associated with one or both of the objects. This difference of almost exactly a factor of two in wavelength for these two (optically) associated objects is either an unfortunate coincidence or a profound mystery.

The discovery of surprising objects such as this tempts us to make statistical arguments. Arguments about rare single events are treacherous; the archives of science are filled with dead hypotheses, supported initially by overwhelming statistical claims. One must avoid the errors of either testing only a single hypothesis, or of selecting an *ad hoc* alternative and then confirming it on the basis of the same data.

Before the observation of double QSOs, the 'most likely' hypothesis was the cosmological hypothesis: Redshifts were cosmological in origin, with a small component due to peculiar velocities. In general QSOs were expected to be randomly distributed on the plane of the sky and any groups that did appear should agree in redshift. Another hypothesis, less definite but existing before these observations, was the local

INTERNATIONAL FOOD INFORMATION SERVICE

Farnham House, Farnham Royal,
Slough SL2 3BN, England.

FOOD SCIENCE AND TECHNOLOGY SUBJECT HEADINGS

The objective of the International Food Information Service is to provide information on all matters concerned with research and development in Food Science and Technology in a form most convenient for users.

Subject headings are:

basic food science (chemistry, physics,
biochemistry, biophysics)
food microbiology
food hygiene and toxicology
food economics
food engineering
food packaging
alcoholic and non-alcoholic beverages
fruit, vegetables and nuts
cocoa and chocolate products

sugars, syrups, starches and candy
cereals and bakery products
fats, oils and margarine
milk and dairy products
eggs and egg products
fish and marine products
meat, poultry and game
food additives, spices and condiments
prepared, synthetic and dietary foods
standards and legislation

IFIS is administered jointly by the Commonwealth Agricultural Bureaux, England; Institut für Dokumentationswesen, Federal Republic of Germany; Institute of Food Technologists, U.S.A.; Centrum voor Landbouwpublikaties en Landbouwodocumentatie, The Netherlands and Zentralstelle für maschinelle Dokumentation, Federal Republic of Germany.

Enquiries about any aspect of the IFIS should be sent to:

INTERNATIONAL FOOD INFORMATION SERVICE

Farnham House, Farnham Royal,
Slough SL2 3BN, England.

ORDER FORM

I wish to subscribe to FSTA for the current volume year; a cheque/money order for £130 is enclosed
I should be grateful for further information on: (tick items of interest)

- ☐ Food Science and Technology Abstracts
- ☐ Food Annotated Bibliographies
- ☐ Photocopies

- ☐ Magnetic Tapes

.....

hypothesis. The observed redshifts were allowed a large, non-cosmological, component and groups of QSOs could now have discordant redshifts.

Our observation of a close pair of QSOs with discordant redshifts is unlikely under the cosmological hypothesis. Sandage and Luyten¹ estimate that there are five QSOs brighter than magnitude 19.4 per square degree. If this is true and if QSOs are randomly distributed in the sky the chance of finding a second QSO within 5 arc s of a given object is approximately 4×10^{-5} . The probability of finding such a pair among the 250 QSOs with known redshifts is about 1 in 100 if there were no observation selection effects. Present observational techniques certainly discriminate against finding close doubles since normally the search is stopped when one candidate from a group of stars is found to be a QSO.

A local hypothesis which puts 10% of the QSOs in pairs of galactic cluster dimensions, say one minute of arc, is at a statistical advantage by a factor of thirty or so. The radio alignment, when accurately measured, may provide additional evidence. The spectral peculiarities are fascinating but no pre-existing theory suggested them and these observations only raise them for future consideration.

We believe that these observations add support to non-cosmological theories of redshifts. Such theories will receive additional support if an interaction between the two components of a close pair can be shown. Alternatively, additional close pairs may be found. Since it is now known that some large redshift QSOs have neutral colours⁸, a search for more QSO pairs should include all stars found near suspected or known QSOs.

We thank Dr Kenneth Nordsieck for assistance during the early August observing run and Dr Robert Carswell for pointing out to us the important paper on the Bowen fluorescence lines. This work was supported, in part, by grants from NSF, NATO, and NASA.

Discrepant Redshifts of QSOs in Clusters of Galaxies and a Close QSO Pair

ALTHOUGH it is the majority view that QSO redshifts are cosmological in origin and related to distance by Hubble's law, several workers¹⁻³ have proposed that QSOs may be more local objects. The strongest direct evidence for the conventional view is provided by observations of a number of QSOs which have been shown to have redshifts (z) which agree to within about 1% with the redshifts of apparently associated clusters of galaxies⁴⁻⁸. These QSO-cluster asso-

ciations have all been found in searches restricted to QSOs with $z < 0.36$ since on the cosmological hypothesis it is only for such low values of z that the associated galaxies would be readily visible. But, as Burbidge and O'Dell⁹ have pointed out, by assuming at the outset that the redshifts are cosmological these investigations fail to test the non-cosmological hypothesis. For the past several years we have been attempting to carry out a study of QSOs in clusters or groups which would be free from this objection. Although our results are by no means complete, we present here some of our preliminary findings as they seem to be of relevance to the present controversy.

To avoid any assumptions as to the nature of the redshifts, two of us (D. J. and C. H.) started, not with a list of QSOs, but with a list of 280 radio sources selected from the 4C catalogue and for which we had measured improved positions. The fields around each of these sources were examined on the Palomar Sky Survey Prints for possible QSO identifications, an identification being suggested whenever a blue stellar object (BSO) brighter than 19 mag was found within the error rectangle of the radio position¹⁰. In searching for possible associations with clusters we adopted the view that a QSO is typically brighter than the brightest cluster galaxies by up to 2 or 3 mag. We therefore noted all cases in which three or more galaxies lay within 1 (arc min)² of the suggested QSO identification and which on the Palomar Sky Survey E print were approximately equal to it in brightness. We noted QSOs with less than three nearby galaxies only if these were brighter than 19 mag and lay within 10 arc s. This approach not only differs from that adopted in other QSO-cluster investigations but also differs significantly from that of Burbidge *et al.*¹¹ who looked for an association between QSOs and much brighter galaxies. It assumes that the QSOs are at cosmologically significant distances rather than very local ones but not necessarily at distances given by Hubble's law.

A search was also made for situations in which more than one BSO lay close to the radio position, a few examples of this type having already been noted¹². It seemed possible that these might represent physical associations of QSOs the significance of which would be easier to establish than QSO-galaxy associations. They would therefore provide a more powerful method of investigating any possible non-cosmological contribution to the QSO redshifts, particularly if this non-cosmological component were present only in high redshift objects, say $z > 1$.

A BSO or possible BSO was found within the search area of fifty-three of the 280 sources examined. Of these fifty-three, two (4C04.54 and 4C28.40) were found to be within 1 arc min of a second BSO, three (4C24.23, 4C11.45 and 4C26.48) lay close to one or more galaxies and the sixth (4C11.50) showed both a close pair of BSOs and a galaxy within the error rectangle. The latter four cases were considered to represent the most probable associations and to be worthy of further study, the remaining forty-nine have been published elsewhere¹⁰. The adopted radio positions of the four selected sources and their position relative to the nearby BSOs are given in Table 1 and enlargements of the fields around each of the sources are shown in Fig. 1.

The most convincing case for a QSO-cluster association is provided by 4C24.23; the BSO is seen clearly near the edge of a small compact group of five galaxies which may represent the brightest members of a cluster extending over a diameter of about 2 arc min. The BSO is the brightest member of the group, consistent with it being a QSO at the same distance. The BSO identified with 4C11.45 is also the brightest member of a small compact group but both the galaxies and the BSO are some 2 mag fainter than in the case of 4C24.23. A line of three brighter galaxies within 2 arc min may be members of the same cluster. 4C26.48 and 4C11.50, each with only a single galaxy within 10 arc s, are less convincing. 4C11.50 was, however, also of par-

Fig. 1 Enlargements from the Palomar Sky Survey Prints of the region around the four sources, the E enlargement being on the left and the O enlargement on the right in each case. The quasistellar objects are marked on the O enlargements, and for 4C11.50 and 4C26.48 the nearby galaxies are marked on the E enlargement. Each picture is about 3 (arc min)^2 and north-east is at the top left hand corner.

ticular interest because of the presence of the two BSOs separated by only a few seconds of arc. The pair of BSOs can be clearly seen on the Palomar O plate although the fainter of the two is barely visible on the E plate which is of rather low quality. The galaxy which is visible only on the E plate is of comparable magnitude to this fainter BSO.

At this stage, because of the low accuracy of the radio positions, it was not certain that the BSOs we had noted were really QSOs rather than chance associations with blue stars. Nor could the possibility be excluded that one or more of them was a radio-quiet QSO with the radio emission originating in one of the nearby galaxies. A search of the literature showed, however, that 4C11.45 and 4C26.48 had already been suggested and confirmed as QSO identifications¹³⁻¹⁵. Since then we have taken optical spectra of

Table 1 Positions of the Four Radio Sources and the Relative Positions of the Optical Identification

4C11.45	13	18	50.0	11	22	30	4.8	4P	5N
4C11.50	15	48	22.0	11	30	00	1.8	6P	12S
4C26.48	16	23	12.8	26	57	30	2.8	12P	12S

4C24.23 using the 200-inch telescope at Palomar and the two BSOs near 4C11.50 have been studied by Baldwin *et al.*¹⁶ at Lick Observatory. Both 4C24.23 and the fainter member of the 4C11.50 pair (4C11.50b) have been confirmed as QSOs and the brighter member of the pair (4C11.50a) was noted as having a continuum spectrum. In addition Ekers (private communication) has determined structures and accurate positions ($\pm 0.5 \text{ arc s}$) for all four radio sources using the Westerbork Aperture Synthesis array, and Fanaroff (private communication) has measured the structure of 4C11.50 using the Cambridge aperture synthesis instrument. Optical positions accurate to about $\pm 0.3 \text{ arc s}$ have been measured by Argue and by Murdoch (private communications).

A full account of these observations will be published elsewhere; at present we note that the accurate optical and radio positions confirm that for 4C24.23, 4C11.45 and 4C26.48 the radio emission does indeed originate in the QSO. The observations of 4C11.50 are particularly interesting since they show that the source is double with a separation of $\sim 15 \text{ arc s}$ in position angle 152° but with one component coincident with 4C11.50a rather than the confirmed QSO, 4C11.50b. This indicates that the source is a 3C273-type double and that 4C11.50a is also a QSO. The separation of the two QSOs is only 4.5 arc s so the possibility that they are physically associated inevitably arises. The nature of 4C11.50a has also been confirmed independently of these radio observations by Wampler *et al.*¹⁷ in a parallel optical investigation and redshifts have been measured for both it and 4C11.50b. A summary of the relevant optical information is given in Table 2.

Although the redshifts of none of the galaxies close to any of the four QSOs have been measured, we estimate from their magnitudes that they cannot in any case exceed a value of approximately 0.3. It can be seen from Table 2 that, apart from 4C11.50b, the QSO redshifts exceed this value of z to such an extent that they cannot be associated with the galaxies if the redshifts of QSOs and galaxies are both distance indicators. The possibility remains, however, that the

No. of (c) regions in which observed	22	38	40	22	6	1	0	1	0	0	0

associations are genuine but that the redshifts are not distance indicators. To support this view it would be necessary to obtain very strong evidence to rule out chance associations. In the absence of evidence showing radio or optical links to the nearby galaxies the only evidence which can be provided must be based on counts of galaxies and clusters of galaxies.

As it has been shown that the radio emission in all four examples arises in the QSO and not in the galaxies or clusters of galaxies, we need to know only the probability that out of the chosen sample of 280 radio sources four quasistellar radio sources will be found in the observed configurations; the probability of a radio-quiet QSO lying close to a galaxy need not be considered. Out of the 280 radio sources, fifty-three were suggested as possibly associated with QSOs with probably 30% representing chance coincidences with blue stars. This indicates that we are dealing with a list containing about forty QSOs which is consistent with the percentage of QSOs (~15%) usually found in source lists at the flux level of the 4C survey. The probability of two cases of a single galaxy being observed within 10 arc s of a QSO is then easily estimated from the published galaxy counts. Counts by Hoskins *et al.*¹⁹ give the probability of a galaxy above +19 mag occurring by chance within 10 arc s of a randomly chosen position as about 0.02 and hence the probability of observing two such cases in a sample of forty QSOs is about 0.3. This ignores the restriction placed on the initial survey of noting only galaxies close to QSOs when they were of comparable magnitude on the Palomar E plate. Even if this were taken into account, however, the probability could not be reduced to a significant level.

The probability that the remaining two QSOs would be observed by chance in small groups of galaxies is more difficult to assess as no figures are available for the surface density of such groups, and in any case the definition of a group is to a large extent subjective. To provide some estimate we have counted the number of galaxies seen above the plate limits in 300 randomly selected regions of sky (a) for 1 (arc min)² centred on each of the chosen points; (b) for 4 (arc min)² centred again on the chosen point; and (c) for 130 such regions we have counted the maximum of galaxies which were observed in any 1 (arc min)² not centred on the chosen point but still containing it. The results of these counts are shown in Table 3. The corresponding number of galaxies observed around 4C24.23 and 4C11.45 is shown in Table 4.

Similar numbers of galaxies would be observed by chance in about one trial in a hundred. In our random counts in most cases where the number of galaxies counted exceeded five per area, they were all at the plate limits, and with our selection criteria would not have been considered as clusters at the same distance as at least the brighter BSOs. A probability of 0.01 is therefore a conservative estimate of the chance of finding a QSO in small groups of the type we

have noted. Adopting this estimate we then find that the probability of finding two such cases in our sample is about 0.08. If the redshifts of the QSOs associated with 4C24.23 and 4C11.45 lay in the region of 0.1 to 0.3, even this probability would have led us to believe that we were dealing with physical associations and that the QSO redshifts are indeed distance indicators.

The probability is, however, too high by some orders of magnitude for our results to lend much support to the non-cosmological hypothesis. Therefore, although the possibility that the associations are genuine cannot be ruled out, the realistic interpretation is that we have simply chance associations of QSOs with small clusters of galaxies. We point out, however, that in their appearance on the Sky Survey Plates, 4C24.23 and 4C11.45 appear at least as convincing QSO-galaxy associations as those which have been used to support the cosmological hypothesis. That the only QSO-galaxy associations suggested prior to a redshift measurement should show discrepant redshifts is at least of some interest, if only to demonstrate that all possible associations do not necessarily support the conventional view.

An examination of the figures of galaxy counts presented here shows that it will be extremely difficult to establish a non-cosmological contribution to the QSO redshifts on the basis of an association with clusters of galaxies unless additional information can be obtained to rule out the possibility of chance associations. The detection near 4C11.50 of a possibly physically associated pair of QSOs seems, however, to offer a more promising approach. Assuming that these are 10⁵ radio-quiet QSOs in the sky brighter than +19 mag (ref. 20), the probability of detecting one within 5 arc s of a quasistellar radio source in a sample of forty such objects is only of the order of 6 × 10⁻⁴. In spite of their different redshifts the probability that we are dealing with a real association is therefore high, particularly as Stockton²¹ has already reported two radio-quiet QSOs separated by only 35 arc s, and which he estimates have a probability of occurring by chance of only 6 × 10⁻³. To establish beyond doubt the existence of associations of QSOs will require many more examples, preferably with more than two members, and it is to be hoped that the examples of two or more blue objects close to the position of a radio source which have already been reported^{19,23} will now be investigated optically. It may be that a significant test of the nature of QSO redshifts is at last in sight. A detailed account of the optical observations of 4C11.50 and their significance is given elsewhere by Wampler *et al.*¹⁷.

We thank those who have provided information prior to publication, N. Argue, R. Ekers, B. Fanaroff, H. Murdoch and M. Schmidt. This work is supported by grants from NATO and NASA. The NAIC is operated by Cornell University under contract to the National Science Foundation and D. L. J. is partially supported by an NSF grant.

Force on a Wire in a Magnetic Field

McCAIG¹ has suggested that a shape factor might be involved in determining the force on a current-carrying wire in a magnetic field when there is a permeability contrast between the wire and its surroundings.

Certainly, the **B** seen by the conduction electrons in the wire would then be different from that present before the wire was inserted, apparently leading to a force which depended on the wire shape and permeability as well as the current, but this then gives difficulties when considering the mutual force between two different wires carrying the same current.

The problem of the cylindrical wire with uniform current density has in fact been solved by Stratton (ref. 2, section 4.21); a simple solution of the more general two-dimensional problem is now presented and discussed. I shall show that there is no shape factor for the force in the general two-dimensional case or for an arbitrary complete circuit. There is, however, a shape factor for the torque.

For simplicity let us consider a two-dimensional equilibrium situation with all quantities independent of *z*, that is, a long straight wire in a transverse field. We wish to calculate the force per unit length required to hold the wire stationary.

The external medium is assumed to be an incompressible fluid; it is homogeneous, isotropic and linear, and has relative permeability μ_e .

Before the wire is inserted there exists a uniform field

$$\mathbf{B}_0 = \mu_e \mu_0 \mathbf{H}_0 = \mu_e \mu_0 H_0 \hat{x}$$

The medium is of sufficient extent, and the field sources sufficiently distant, that the insertion of the wire does not significantly alter the reluctance seen by the sources. Nor are the sources affected by the field of the current.

The long straight wire carries a current $I_0 = I_0 \hat{z}$. The wire can have arbitrary mechanical and electrical properties, arbitrary cross-section, and arbitrary current distribution across it provided all these are independent of *z*.

The field produced by the current will in general not be circular, and inserting the wire into the field will also distort $\mathbf{H}_0$. Outside the wire the total field **H** (strictly $\mathbf{B}/\mu_e \mu_0$) can be expressed in terms of a vector potential

$$\mathbf{H} = \text{curl}[\mathbf{T}(\rho, \lambda) \hat{z}]$$

with

$$\nabla^2 T = 0.$$

The appropriate solution for *T* is

$$T = H_0 y + a_0 \ln(1/\rho) + \sum_{n=1}^{\infty} \rho^{-n} (a_n \cos n\lambda + b_n \sin n\lambda)$$

corresponding to $H_0 \hat{x}$, a circular field $a_0 \hat{\lambda}/\rho$, and line dipole, quadrupole (and so on) fields proportional to a_n/ρ^{n+1} . Only the circular field contributes to $\oint \mathbf{H} \cdot d\mathbf{l}$ taken round a circle, so $a_0 = I_0/2\pi$, independent of the choice of origin.

The force of electromagnetic origin acting on the wire will come from both body forces (magnetic forces on the current and on the magnetisation) and surface forces (non-uniform pressure of the surrounding fluid). Fortunately it is the total force which is given by integrating the Maxwell stress over any surface surrounding the wire and entirely in the fluid (ref. 2, section 2.29):

$$\mathbf{F} = \mu_e \mu_0 \oint [(\mathbf{H} \cdot \hat{n}) \mathbf{H} - (1/2) H^2 \hat{n}] dS$$

where **H** is the total field.

Let us make the integration surface the cylinder $\rho = a$. (It is easily shown that the ends do not contribute.) In equilibrium the force cannot depend on the radius of this surface, so the only non-zero contribution to the integral must come from the interaction of the uniform field $\mathbf{H}_0$ with the circular field $\mathbf{H}_1 = I_0 \hat{\theta}/2\pi\rho$. Keeping only these terms, and remembering $\mathbf{H}_1 \cdot \hat{n} = 0$, it follows that

$$\mathbf{F} = \mu_e \mu_0 \oint [(\mathbf{H}_0 \cdot \hat{n}) \mathbf{H}_1 - (\mathbf{H}_0 \cdot \mathbf{H}_1) \hat{n}] dS$$

Performing the integration we find the force per unit length to be

$$\mathbf{f} = I_0 \mu_e \mu_0 H_0 \hat{y} = I_0 B_0 \hat{y} = \mathbf{I}_0 \times \mathbf{B}_0$$

Thus the force on the wire depends only on the total current it carries, and on the value of the uniform $\mathbf{B}_0$ present before the wire was inserted; it is independent of the shape and material of the wire, and the distribution of current in it.

Therefore the total electromagnetic force per unit length of the long straight wire is simply $\mathbf{I}_0 \times \mathbf{B}_0$. Unfortunately it does not seem possible to give a simple interpretation of this overall result in terms of the various forces acting on the wire.

To indicate the complexity of the problem, consider the much simpler situation when there is no $\mathbf{B}_0$, but only the current $\mathbf{I}_0$. One can see physically that provided the fluid has uniform permeability, and (effectively) extends to infinity, there is no reason for there to be any net force on the wire. That the net force is zero is confirmed very quickly by the Maxwell stress argument used above. However, let us consider the individual forces.

There will be induced magnetisation $\mathbf{M}(\rho, \lambda)$ in the fluid and in the material of the wire. The total field $\mathbf{B}(\rho, \lambda)$ can be expressed as $\mathbf{B} = \mathbf{B}_f + \mathbf{B}_i + \mathbf{B}_e$, where $\mathbf{B}_f$ is that field which would be given by the current I_0 in free space, $\mathbf{B}_i$ that from the (internal) wire magnetisation, and $\mathbf{B}_e$ that from the (external) fluid magnetisation.

The resultant body force on the wire will come not only from the integral of the Lorenz force $\mathbf{j}_0 \times \mathbf{B}$, but also from the integral of the force $(\mathbf{M} \cdot \nabla) \mathbf{B}$ exerted on the wire magnetisation by the gradient of **B**. Many of the contributions must cancel on integration, because they correspond to the 'action' and 'reaction' of forces between different parts and properties of the wire, but two terms are left. These are the volume integrals of $\mathbf{j}_0 \times \mathbf{B}_e$ and $(\mathbf{M} \cdot \nabla) \mathbf{B}_e$, both involving the field whose source is the (non-uniform) magnetisation of the surrounding fluid.

In addition to these body forces there will also be a surface force given by the integration of the (non-uniform non-

isotropic) fluid pressure of magnetic origin; this third term also derives from the non-uniform magnetisation of the fluid. (Any hydrostatic pressure of gravitational origin will, for our incompressible fluid, be unaffected by the presence or absence of magnetic fields.)

The total force is, however, zero. Therefore either the integrated effects of the three terms are individually zero or the three effects are non-zero but cancel. That the forces are individually zero is reasonable for simple geometries but most unlikely for arbitrary geometry, so, even in this apparently simple situation, in general there must be a complicated balance between the body forces and surface forces which arise from the magnetisation of the fluid.

In the more general case with a $\mathbf{B}_0$ there must be an even more complicated partial balance between the three types of force ($\mathbf{j} \times \mathbf{B}$, $(\mathbf{M} \cdot \nabla)\mathbf{B}$, and surface pressure), and one can only be thankful that the Maxwell stress approach avoids the need to calculate them individually.

The net result is, however, that, in this two-dimensional situation in a given fluid, long straight wires of whatever material or cross section carrying the same current experience the same force; there is no need for a shape factor, as suggested by McCaig¹. (He was, however, correct in suggesting that the solution to his problem might lie (partly) in pressure surface forces.) (If $\mathbf{B}_0$ is in fact produced by, say, a parallel wire in a different medium, then the forces on the two wires are not equal and opposite, but the difference is the force required to keep stationary the boundary between the two media.)

Whatever the details of the force balance which leads to this simple result in the two-dimensional case, there is no guarantee that the same balance will hold in more complicated geometries. Nor can the Maxwell stress approach then be used, because it is no longer possible to integrate over a surface (effectively) entirely in the fluid. The force on a complete circuit can, however, be determined.

In fact there is no net force on a complete circuit in a uniform $\mathbf{B}_0$. (This can be seen by integrating the Maxwell stress over a spherical surface enclosing the circuit; by the same type of argument as used above, the only type of field of internal origin which can give a non-zero force by interaction with the uniform $\mathbf{B}_0$ is that of a monopole.) We can therefore say that the two-dimensional result that the force on a wire does not contain a shape factor is valid also for the (zero) force on a complete circuit.

Although plausible, it has not been shown that the result holds for any portion of a circuit.

Although the force on a straight wire or complete circuit has been shown to be independent of shape and of permeability contrast, this is not true for the torque. Even in the two-dimensional case, any line-dipole field produced by the wire will give a torque; although the current itself cannot directly produce such a field it can induce a net line-dipole moment in any asymmetric permeability contrast.

In the more general situation of a complete circuit this contribution to the torque still exists, but there will now be other, probably larger, contributions. Consider, for example, a rectangular coil; the wire on one side of the coil will be magnetised by the field of the current in the opposite side, and will give an additional dipole moment, and hence torque, which will depend on the permeability contrast between the wire and the fluid.

McCaig's discussion was prompted by the experiment of Whitworth and Stopes-Roe³. They adjusted the current in a coil until the torque on the coil balanced the torque on a permanent magnet fastened to the coil, when both were immersed first in water and then in a paramagnetic fluid. In fact a rough estimate shows that the above effect would reduce the current change by about 5%.

I thank Dr R. W. Whitworth for discussions.

Evidence for the Opening of the South Atlantic in the Early Cretaceous

ONE of the cornerstones of continental drift is the fit¹ of the continental edges of Africa and South America by removal of the South Atlantic Ocean, which is thought to have formed by the rifting of these two continents some time in the Mesozoic and their subsequent drifting apart. We shall present evidence from marine magnetic anomalies in the southern South Atlantic that demonstrates that this initial rift first occurred in the early Cretaceous, probably in the Valanginian (~125 to 130 m.y. BP). This conclusion is based mainly on a magnetic lineation pattern that lies in the Cape Basin directly south-west of the continental edge of South Africa, although we very tentatively identify a few of the same anomalies on the other side of the ridge in the Argentine Basin.

West of Cape Town, South Africa, in the Cape Basin, there occurs a sequence of north-west trending magnetic anomalies which indicates that seafloor spreading took place from 130 to 110 m.y. BP (Fig. 1). In the Argentine Basin, possible correlative anomalies are identified, though their definition in the Argentine Basin is poorer than in the Cape Basin. As can be seen in Fig. 1, the anomalies (which we will call the Cape sequence) can be traced in the Cape Basin from 34° S to 40° S. A lack of properly oriented track lines prevents identification further south. Track lines immediately to the north of 34° S, though properly oriented, do not show the anomalies.

To the west of the lineated anomalies, the magnetic field is characterised by irregular, low amplitude anomalies which do not correlate from track to track. One has to go west to 4° E before encountering the lineated anomalies of the late Creta-

Fig. 1 Magnetic lineation chart of the Cape Basin off South Africa. Mesozoic magnetic lineations are labelled M. Lineation labelled G is the edge of the African continent defined by a steep gravity gradient by Talwani and Eldholm². The stippled pattern is an area of very small magnetic anomalies that corresponds to the submarine portion of the African continent³. Mapped fracture zones are shown with bold, solid or dashed lines. Synthetic fracture zones drawn as small circles about the pole of early opening⁹ are shown with dotted lines. Ship tracks are thin, solid lines. Magnetic anomaly data collected on the

Fig. 2 Magnetic anomaly profiles across the Cape Basin lineations shown projected to a direction perpendicular to the structure. FZ is the small fracture zone offset shown also in Fig. 1. M lineations are from Larson and Pitman⁵. The magnetic block-model was made by combining the Mesozoic reversal time scale⁵ with a spreading half rate of 1.6 cm yr⁻¹. The direction of remanent magnetisation is inclination=60° up, declination=30° W, in accord with a palaeomagnetic pole location for Mesozoic Africa at 65° S, 82° E (ref. 6).

ceous-Cainozoic reversal sequence which cover the mid-ocean ridge. Northward the Cape sequence trends into the marginal smooth zone defined² on the basis of aeromagnetic data. In the area of the Cape sequence, the aeromagnetic data reveal a sequence similar to that derived from the ship data used here. We do not show aeromagnetic data because the positions of magnetic anomalies so determined are offset several miles with respect to ours, and thus we suspect that the aircraft navigation is slightly in error.

To the east, the Cape sequence borders the continental margin as defined by Talwani and Eldholm³ using gravity and magnetic data. They suggested that the boundary between oceanic crust and continental crust is marked by a steep gradient in the isostatic gravity anomaly that lies at the edge of the continental structure. This gradient is nearly coincident with a change in the magnetic signature from a smooth, almost featureless magnetic field over the continental shelf and upper slope seaward to a region characterised by relatively large amplitude anomalies similar in magnitude and width to recognised seafloor spreading anomalies. It is these anomalies seaward of the upper continental slope that we have correlated with early Cretaceous anomalies recognised in the North Atlantic and North Pacific^{4,5}.

The correlations can be seen in Fig. 2 where the magnetic data were projected from several ship tracks on to a line trending N 55° E. At the top of Fig. 2 is a model computed using the Mesozoic reversal sequence⁵ determined by correlating the Mesozoic lineations in the North Pacific with the Keathley sequence in the North Atlantic. A mean Mesozoic palaeomagnetic pole at 65° S, 82° E (ref. 6) was used to determine the remanent magnetic direction for the model.

We consider the correlations, both from track to track and with the model, of anomalies M-1 to M-5 to be excellent. Note especially the well developed and well reproduced shapes of anomalies M-3 and M-4 and the spacing of anomalies M-2, 3 and 4. Anomalies M-6 and M-7 are usually present as modelled, but the lineation of the anomalies older than M-7 and their comparison with the model is often poor. We attribute at least some of this poorer correlation to disruption of the lineation pattern by the initial rifting phenomenon and point out that our identification of these anomalies as an expression of the Mesozoic reversal pattern rests almost wholly on evidence from the younger portion of the sequence. The oldest anomaly (Fig. 2) next to the continental edge is a well lineated negative feature that could be M-13, or the edge of the African continent³. Our model shows it as a reversal, but a non-magnetic (continental) block at this point would not change the shape appreciably.

The most disturbing part of this interpretation is the negative magnetic lineation that always occurs to the west of (younger than) anomaly M-1 (Fig. 2). This anomaly does not consistently occur in this position with respect to other Mesozoic lineation sequences^{4,5} although three negative lineations have been correlated⁷ east of (younger than) the Keathley sequence that may be related to the Bermuda Discontinuity. If our interpretation of these lineations in the Cape Basin as Mesozoic magnetic anomalies proves correct, it will be necessary to introduce another reversal into the magnetic time scale that is just younger than M-1.

A slight offset in anomalies M-1 to M-7 south of line 1314-1 indicates a fracture zone. On checking the seismic reflection profiler records, we were able to find additional evidence of a fracture zone in the area suggested by the magnetic lineations. The fracture zone shows up as discontinuities in basement topography, particularly as basement peaks. The peaks appear in the magnetic data as large, isolated, positive anomalies on tracks 1103 and 1314-1. This fracture zone parallels the Agulhas Fracture Zone^{3,8} to the south that appears in magnetic data as a large positive peak that parallels the south-east edge of the Agulhas plateau. In Fig. 1 we have drawn for comparison synthetic fracture zones about the early opening pole based on fracture zones in the central Atlantic⁹. The trends of the synthetic fracture zones are nearly identical to the trends of the two observed fracture zones. The fact that the trends of these fracture zones match the synthetic trends is additional evidence that offsets and lineations of the continental margins have recorded the directions of motion during the early opening⁹. In particular, the Agulhas Fracture Zone is the African counterpart of the Falkland Plateau scarp, a conclusion that was reached more qualitatively by observation of the trend of the south-eastern edge of the African continent by Francheteau and Le Pichon¹⁰, and by observation of a buried marginal ridge on the south-east side of the Agulhas Plateau by Scrutton and du Plessis³.

In the western Argentine Basin magnetic anomalies for the most part are subdued and display no coherence from track to track; however, four tracks from the Lamont data library over the lower continental rise off Argentina display two large positive anomalies that are consistent from track to track. There also seems to be a left lateral offset in the anomaly lineation pattern. The spacing is similar to anomalies M-2 to M-4 of the Cape sequence. Also, they are at about the same latitude relative to the pole of rotation as the Cape sequence, lie about the same angular distance from the continental slope as M-2 to M-4 in the Cape Basin, and their spacing shows the

same half-spreading rate. The above observations taken together indicate that some of the Mesozoic anomalies of the Cape sequence are also present in the Argentine Basin. We do not understand why they are not as well-developed in the Argentine Basin. Model studies indicate that the greater depth to basement (~ 8 km) in the Argentine Basin will not attenuate the anomalies as much as observed.

Assuming that our anomaly identifications in both the Cape Basin and the Argentine Basin are correct and accepting the Talwani and Eldholm³ analysis of the continental margin west of Cape Town, a consistent picture is obtained by drawing the ocean basin and continents as they were at the time of formation of anomaly M-2. If the ocean is closed completely using the rotation to the 500-fathom line, a large (~ 100 km) gap is left open west of Cape Town. The extension of the African continent westward of the 500 fathom line as suggested by Talwani and Eldholm³ partially fills this gap.

Using the early opening pole⁹, we rotated anomaly M-2 of the Cape sequence back to the continental edge as defined by Talwani and Eldholm³. An angle of 2.3° is necessary for this rotation. This angle will represent half the motion of South America with respect to Africa between the initial rift and anomaly M-2. If South America, together with anomaly M-2 from the Argentine Basin, is rotated westward from the 500-fathom fit to Africa¹ by 4.6° (twice 2.3°) about the early opening pole⁹, the anomalies M-2 of the Argentine Basin nearly coincide with anomalies M-2 of the Cape Basin (Fig. 3). It is also apparent (Fig. 3) that the proposed left-lateral offset in the Argentine Basin then corresponds in position, sense and amount of offset with the small fracture zone that we identify in the Cape Basin.

Thus, our identification of the Mesozoic anomalies on both sides of the South Atlantic, Talwani and Eldholm's³ definition of the edge of the continent west of South Africa, and the 500-fathom average fit of the entire South American and African margins¹ are internally consistent. This suggests that the 500-fathom line may be a good average definition of the edge of the continent though locally (in the Cape Basin) there are deviations from this average.

Larson and Pitman⁵ did not recognise these Mesozoic magnetic lineations in the Cape and Argentine Basins and thus suggested that the South Atlantic did not begin to open until, or subsequent to, 110 m.y. BP. Our identification of these anomalies corrects this suggestion, but does not appreciably change their calculation of the rate of rapid spreading in the South Atlantic from 85 to 110 m.y. BP. It seems to lower the rate for that period by about 10%; for instance, at 40° S latitude the rate drops from about 5 to about 4.5 cm yr^{-1} . For the time period 110 to 127 m.y. BP the spreading rate is 1.6 cm yr^{-1} (see Fig. 2).

Figure 3 shows a reconstruction of Africa and South America at 112 m.y. BP (anomaly M-2 time) accomplished by the rotations just described. The relative proximity of the pole of rotation (21° N, 14° W)⁹ resulted in the early opening up to at least 112 m.y. BP occurring somewhat as a scissors-type motion. The lineations in the southern South Atlantic were generated in accord with motion at that latitude, while the northern South Atlantic remained more nearly closed. The close proximity of northern South America to northern Africa until at least 110 m.y. BP is in accord with palaeontological and stratigraphical studies in Brazil and Gabon that show freshwater lake deposits near or at the rifted coastlines throughout the Neocomian (~ 135 to 112 m.y. BP)^{11,12}. These were followed in the Aptian (~ 112 to 105 m.y. BP) by salt deposits in the same approximate locations^{11,13,14}. Because there is little motion between northern Africa and northern South America, it is not obviously necessary to resort to forming these deposits behind dams that cut off the southern Neocomian and Aptian Seas, although the Walvis Ridge and Rio Grande Rise could have acted as such structures (R. Leyden and J. R. Nunes, to be published). Finally, by Albian time (~ 105 to 100 m.y. BP) a wide, shallow marine transgression occurred

Fig. 3 Palaeogeographical reconstruction of the South Atlantic at 112 m.y. BP (anomaly M-2 time). The reconstruction was made for Africa and the Cape Basin lineations (+) in their present positions by rotating South America and the Argentine Basin lineations (x) first by $+57.0^\circ$ about a pole at 44° N, 30.6° W (ref. 1), and then by -4.6° about a pole at 21.5° N, 14° W (ref. 9). These manipulations bring the M-2 lineation of the Argentine Basin into near coincidence with the M-2 lineation of the Cape Basin.

and the northern South Atlantic was completely open for the first time¹¹.

The oldest magnetic lineations in the Cape Basin are also in close agreement with the ages of the Serra Geral basalts in Brazil that date the initial rifting in that region at 120 to 130 m.y. BP¹⁵ and the Kaoko basalts of south-west Africa whose radiometric age is 114 to 130 m.y. BP¹⁶. The age of the oldest magnetic lineations (~ 127 m.y. BP, anomaly M-12) is also coincident with the marine transgression of southern Africa, southern Chile, and southern Argentina during the Upper Valanginian (~ 127 to 124 m.y. BP)¹². It seems to us that this marine transgression is the direct result of the pattern of early rifting described above. Hallam¹⁷ and Reymont¹¹ studied the palaeontological associations of Lower Cretaceous formations of South America and Africa and concluded that there is enough similarity of the faunas to demonstrate that only a narrow seaway separated Africa from South America during the Neocomian. The Upper Valanginian marine transgression suggested to Reymont and Tait¹² that this was the time that the land masses began to drift apart. Fossil evidence along the south-east coast of Brazil and the western coast of Africa indicates that by Upper Aptian time an arm of the sea had extended northward at least as far as Sergipe and Gabon. The distribution of nektonic ammonite shells indicates that the North and South Atlantic were finally joined in the Lower Turonian, as land connections between Africa and South America in equatorial regions were severed.

We agree that during the Valanginian only a narrow seaway separated Africa from South America because that is the age of M-12, the anomaly that dates the onset of continental drift. We speculate that the Valanginian was not only the time of the initial opening of the South Atlantic, but also of the more

general breakup of Gondwanaland. As the nearest pole of rotation lies to the north, the spreading rate on the ridge that created the Cape Basin lineations must have increased towards the south. Thus, somewhere south of the Cape Basin this ridge met a triple junction, or was transformed to another spreading centre with a faster rate. It is unlikely that the ridge could have been transformed between Antarctica and South America into the Pacific because the Palaeozoic and Mesozoic formations on these continents form continuous sequences that were not fragmented into the Scotia Arc until at least the end of the Andean Orogeny in the Cainozoic¹⁸.

Thus, the ridge was probably transformed to the east into the newly forming Indian Ocean or between the two stable masses that now form east and west Antarctica. The former suggestion is similar to that made by McKenzie and Sclater¹⁹ for the plate boundaries in this area from 75 to 55 m.y. BP. It is an hypothesis that awaits testing by determining the presence or absence of the Mesozoic lineation pattern at the stable margins of the Indian Ocean.

We thank Manik Talwani and Olav Eldholm for pointing out to us the existence of magnetic lineations in the Cape Basin. This research has been sponsored by the US Office of Naval Research and by a grant from the Oceanography Section of the National Science Foundation to the Lamont-Doherty Geological Observatory.

World-wide Source of Leaf-derived Freezing Nuclei

INITIATION of precipitation over much of the Earth's surface is believed to be intimately related to the development of ice in supercooled clouds. The source, composition and number of small particles (ice nuclei) initiating freezing events in natural clouds are poorly understood. These particles represent a very small fraction of the total aerosol in the atmosphere. The material most frequently held to

represent the majority of ice nuclei are clays, especially kaolin.

In a summary of earlier research, we reported^{1,2} that decomposed plant leaf litters contain large numbers of freezing nuclei and that these nuclei are perhaps responsible for the nucleating abilities of soil particles. (Freezing nuclei are defined as particles capable of nucleating ice in supercooled water. If no distinction is made between freezing and deposition the nuclei are referred to as ice nuclei.) The leaf-derived nuclei (LDN) were found to initiate freezing of supercooled water drops at temperatures warmer than -5°C and to occur in concentrations of up to 10^{10} nuclei active at -10°C per g of decaying leaf. The conclusion that the nuclei are products of decomposition was reached by following the decay of fresh leaves in the laboratory and observing the gradual evolution of nuclei to the stage comparable to naturally decomposed litters. (Extensive chemical analyses have not yet revealed the structure of the LDN but indicate that the nucleating particles probably constitute less than 0.1% of the total decayed leaf litter mass. Filtration tests suggest that the LDN particles are between 0.1 and $0.05\text{ }\mu\text{m}$ in diameter. Heat in excess of 60°C deactivates the nuclei, supporting the suggestion that they are organic in nature.) Though it has not yet been shown that the mechanisms transferring LDN to the atmosphere are of sufficient intensity to account for atmospheric ice nucleus concentrations, it was felt important to establish the extent to which LDN are available on a global basis.

We collected samples of well decayed litter from fifty different dominant tree or grass species across the northern hemisphere. The sampling locations were spread throughout North America, from the Pacific to the Atlantic, and across Europe and northern Asia from Britain eastward through Siberia to Japan. A second set of samples was collected along a transect from Japan through southeast Asia into western India.

Testing of the little samples for freezing nucleus content was done in a standardised manner by inserting 1 g (dry weight) of leaf material into 100 g of distilled water followed by agitation and a 5-min settling period. The resulting suspension was filtered through a paper filter with a pore size of approximately $50\text{ }\mu\text{m}$. The slightly turbid filtrate was tested on a nucleus spectrometer following the principles and procedures outlined by Vali³.

Numerous samples were found to contain freezing nuclei in numbers comparable with what has been reported earlier². Some other samples were found to contain fewer ice nuclei, by factors of up to 10^5 . The abundance of nuclei in a sample appeared not to be correlated with species but showed a closer similarity to samples from the same geographical location. On closer analysis it became apparent that nucleus content is closely related to the climate prevailing at the sample's origin, almost regardless of the species of plant.

According to Köppen⁴, the Earth is divided into six principal climatic zones depending on seasonal temperature and variation, precipitation pattern, and physiography. Of the six zones, three have extensive vegetation (A, tropical; C, humid mesothermal; D, microthermal) and the remaining three have lesser amounts of vegetation (B, dry; E, polar; H, undifferentiated highlands). The type of vegetation growing in each climatic zone is very distinctive for that zone. Data are presented in Fig. 1 for three climatic zones for which a minimum of twelve nucleus spectra per zone is available. For each climatic zone, the highest, lowest and median spectra are plotted. A clear separation between the three zones is evident.

Samples of the genus *Poa* were collected from each of the climatic zones A, C and D. The nucleus contents of the three samples were found to coincide with the typical spectra for each of the zones. Samples of the genera

Fagus, *Oryza*, *Populus* and others were available from two of the climatic zones. In each case the nucleus content followed the climatic trend. Thus, ice nucleus content can be clearly seen to depend primarily on the climate of a sample's origin; it is also evident that the range of nucleus contents for samples from a given zone is quite restricted.

Fig. 1 Freezing nucleus spectra of well decayed leaf litters from A, C and D-type climate zones. For each zone, the highest, lowest and median spectra are plotted.

What factors cause the close tie between nucleus content and climate of growth? Since the process of formation of the freezing nuclei from leaf matter is not yet known, the reasons can only be speculated upon. It is known in general that decomposition is mediated by bacteria and the specific role of bacteria in producing freezing nuclei from leaf matter was demonstrated by Fresh⁵. Differences in microflora among climatic regions might thus be one of the factors. Others of possible importance are the availability of moisture, average air temperature and type of soil substrate.

The climatic dependence of freezing nucleus content in leaf litters does not make itself evident in the concentrations of airborne ice nuclei which have been found to be fairly constant globally⁶. Atmospheric mixing and the possibility that the release of nuclei from litters may also be variable with climate, in an inverse way compared with the availability of nuclei, may account for the observations.

In summary, the world-wide availability of LDN

strengthens the suggestion that LDN may constitute a significant fraction of the atmospheric ice nuclei.

BIOLOGICAL SCIENCES

Rapid Screening Assay for Revertants derived from MSV-transformed Cells

MURINE sarcoma virus (MSV)-transformed 3T3FL cells (S⁺L⁻ cells¹) produced spontaneously and at variable rates flat variants (revertants) from which MSV could no longer be rescued by superinfection with murine leukaemia virus (MuLV)^{2,3}. During the course of investigation of reversion frequency in S⁺L⁻ cells, we have been able to detect revertants by a rapid screening assay technique instead of using the more cumbersome cloning procedure in microtitre wells as previously described^{2,3}. The S⁺L⁻ cell line 3197¹⁻³ was composed of hyper-refractile, loosely attached cells and did not form a compact cell monolayer. Infection of this cell line with MuLV changed the cellular morphology to a slightly more rounded cell type, and increased the tendency of cells to detach readily from the surface of the container. When rescue-negative revertants derived from S⁺L⁻ cells were infected with MuLV there was no observable change in cellular morphology. These characteristics can be used as the basis for a rapid screening assay technique for revertants from S⁺L⁻ cells, the details of which are described here.

The sublines of 3197 cells, 3-321 and 3-360 (ref. 4), grown in modified McCoy's 5a medium with 10% foetal calf serum (Grand Island Biological Co.) were infected with the IC isolate of Moloney leukaemia virus⁵ at MOI > 5 focus inducing units (FIU)⁶, and 1,000–5,000 cells in 5 ml medium were delivered into 25 cm² flasks (Falcon). Flasks were incubated at 37° C for 4 d, then shaken to detach the relatively loose S⁺L⁻ cells; supernatant was removed and flasks were washed twice with medium. Five millilitres of fresh medium were added and flasks were further incubated at 37° C. After a further 3–5 d of incubation, flat, contact-inhibited revertant cell colonies formed and were counted. When S⁺L⁻ cells were infected with MuLV at high MOI (> 5 FIU), MSV was rescued from them about 12 h after infection⁷. At that time, viral interference had developed in rescue-negative revertant cells following MuLV infection, and no transformation of revertants was produced by the rescued MSV. Therefore, revertants remained flat and formed colonies.

The sensitivity of this technique in the detection of revertants was compared with that of cloning techniques^{2,3} in which flat cell colonies were isolated in microtitre wells (Micro Test II tissue culture plate, Falcon) and then tested for rescuable MSV genome by superinfection with MuLV^{1-3,7}. Quantitatively, these two assays gave results which were in close agreement, with the following reversion frequencies: 0.0002 and 0.0003 in 3-321 cultures, and 0.003 and 0.005 in 3-360 cultures, as can be seen in Table 1.

Fig. 1 Reconstruction experiment. Mixtures containing 200 (1), 100 (2), 50 (3), 200 (4) and 0 (5) MSV-revertant cells plus 10,000 S⁺L⁻ cells were seeded into flasks and (1), (2) and (3) were simultaneously infected with MuLV. On day 4, cultures (1-3) were shaken, washed and refed. Photographs were taken after staining on day 9.

The reliability of the rapid screening assay technique for revertants was assured by the following reconstruction experiment. Mixtures containing 400, 200, 100, 50 and 25 revertant 3D-2-14 cells³ plus a constant number (10,000) of 3-321 cells were distributed into flasks, four per group, in the presence or absence of MuLV. At 4 d, cultures were shaken, washed and refed as described above. On day 9, cultures were fixed and stained with Giemsa, and colonies of revertant cells were counted. The average number of revertants in the infected groups was 186, 100, 48.3, 24.5 and 10, respectively. Some stained cultures are shown in Fig. 1. An average cloning efficiency of all groups was 47% which was similar to that of 3D-2-14 cell alone (42%). In uninfected flasks, colonies were small and fewer colonies ($\frac{1}{4}$ the number in the infected group) were observed. This seemed to result from an interference with the growth of the revertants by an excess of S⁺L⁻ cells. These findings, nonetheless, indicated that the rapid screening assay technique allowed detection of revertant colonies in mixed populations containing a large excess of transformed cells.

This rapid screening assay procedure is not only useful for determination of the spontaneous reversion frequency in S⁺L⁻ cells, but is also valuable for the study of the effects on MSV-transformed cells of physical, chemical and biological agents which enhance the frequency of reversion⁴. Two million 3-321 cells, whose reversion frequency was lower than 0.0003, were exposed to 20 ml of medium containing various concentra-

tions of fluorodeoxyuridine (FUdR) for 1 h at 37° C. At the end of the exposure period, medium containing FUdR was removed, cells were washed twice with medium and dispersed, and 100 cells were plated into 60×15 mm plastic plates (cloning technique), or 1,000 cells were delivered, in the presence of MuLV (MOI>5 FIU), into flasks for rapid screening assay. More than ten plates or flasks were used for each concentration of chemical. On day 8, flasks were examined for the presence of revertant colonies. The results of dose-response in the derivation of revertants from S⁺L⁻ cells are presented in Fig. 2; the optimum dosage of FUdR was 15 μ g ml⁻¹ which produced a reversion frequency of 0.008, and the same efficiency of revertant detection was found by both techniques. Accordingly, FUdR can be considered as increasing the spontaneous reversion frequency by about thirty-fold. The observed decrease in reversion frequency by high concentrations of FUdR cannot be explained solely on the basis of reduction in cloning efficiency⁴.

Fig. 2 Dose-response of FUdR in the induction of revertants from S⁺L⁻ cells. S⁺L⁻ cells were treated with various concentrations of FUdR for 1 h at 37° C. At the end of the exposure period, cells were washed and plated at a concentration of 100 cells per plate for cloning technique (●) or 1,000 MuLV-infected cells per flask for rapid screening assay technique (○). On days 7 to 9, frequencies of revertants were determined.

Table 1 Comparison of Sensitivity of Detection of Revertants from S⁺L⁻ Cells by Cloning and Rapid Screening Assay Technique

S+K ⁻ subline	Assay technique	No. of cells plated	No. of revertants*	Average frequency
3-321	Cloning	Microtitre wells†		
		1,000	0	
		800	0	
		500	0	0.00018
	Plates‡	12,500	3	
		1,100	0	
		500	0	
3-360	Rapid screening	51,200	11	
		16,000	4	0.00026
		10,000	5	
	Cloning	Microtitre wells		
		200	1	0.005
	Rapid screening	400	2	
		10,000	33	0.0033

* Flat and rescue-negative.

† Plates 0.2 ml of cell suspension containing 1 cell ml⁻¹.

‡ Because of their low reversion frequency, cells were seeded into plastic plates (60×15 mm) at a concentration of 100 cells per plate. On day 9, flat cell colonies were isolated and recloned in microtitre wells.

Preliminary data with Kirsten MSV nonproducer Balb/3T3 cells⁸ similarly demonstrated that the reversion frequencies of a rescue-negative revertant were 0.001 by the cloning technique and 0.0009 by the rapid screening assay procedure. Another subline of S⁺L⁻ cells, FG-10 (refs 1 and 2), revealed reversion frequencies of 0.02 by both procedures.

In summary, the rapid screening assay procedure is a simple and convenient method for the detection and quantitation of MSV-revertants, and is comparable in sensitivity to the cloning technique. It may also prove useful for the investigation of the reversion effects of a variety of agents on transformed cells.

We thank Dr Robert H. Bassin for helpful discussion and Ida M. Gaines for technical assistance.

Prostaglandins as Potentiators of Increased Vascular Permeability in Inflammation

PROSTAGLANDINS are released in inflammatory reactions in animals¹ and in man². The observation that non-steroidal anti-inflammatory agents inhibit prostaglandin synthesis *in vitro*^{3,4} and *in vivo*⁵, and that the comparative potency of these anti-inflammatory compounds is the same *in vitro* and *in vivo* as inhibitors of carrageenin-induced oedema⁶, suggests that prostaglandins may have an important role in inflammation. Prostaglandins (E₁, E₂, F_{1a} and F_{2a}) evoke increased vascular permeability in the skin of rat and man⁷, which appears to be an indirect effect resulting from mast cell degranulation. The lack of potency of prostaglandins in causing increased vascular permeability on intradermal injection in the guinea pig⁸ has, however, received little attention. We have confirmed this observation (Fig. 1, Table 1) and conclude that in the guinea pig prostaglandins cannot be regarded as chemical mediators which act directly on the vascular endothelium as do histamine, serotonin (5-hydroxytryptamine) and bradykinin. We have therefore investigated a possible alternative role for prostaglandins in inflammatory mechanisms.

The widespread occurrence of prostaglandins in animal tissues together with their mode of action on a wide range of physiological systems has led to the proposition that these substances may have a general function as modulators of cellular responses to a variety of stimuli⁹ (for example, to hormones, neurosecretions, neural transmitters and electrical stimulation). Examples of physiological systems in which prostaglandins may act as modulators include: fatty acid and glycerol production by the epididymal fat pad in response

to adrenocorticotrophic hormone (ACTH) or glucagon¹⁰; altered permeability to water in the toad bladder in response to vasopressin¹¹; gastric secretion in the rat in response to pentagastrin¹²; smooth muscle contraction in response to sympathomimetic amines¹³, and transmitter release from pre-synaptic nerve terminals following stimulation of the splenic nerve¹⁴. An analogous situation is that of cutaneous pain in man where prostaglandins in conjunction with agonists were shown to induce hyperalgesia and overt pain¹⁵. We have therefore investigated the possibility that prostaglandins may act as modulators of inflammatory reactions. Should prostaglandins modulate altered vascular permeability, two possible sites of action are the microvascular bed itself, or adjacent cells which release inflammatory mediators.

Table 1 Effect of Intradermal Injection of Prostaglandin on Inflammatory Lesions Induced by Histamine and Bradykinin

Dose of material (μg)	Response ± s.d. (count in lesion/count in 1 μl blood)	Difference (count in lesion/count in 1 μl blood)	Significance (P) (paired t-test)

Saline	22.9 ± 6.4	—	
Uninjected skin	12.4 ± 1.0	—	

Fig. 1 Dose-response curves in guinea pig skin. Responses represent mean ¹²⁵I-albumin count in lesion/count in 1 μl blood (± 95% confidence limits). *a*, Bradykinin (●); bradykinin mixed with a constant dose (1 μg per 0.1 ml) of PGE₁ (○). *b*, PGE₁ (▲); intradermal saline (0.1 ml) (■).

To ascertain whether prostaglandins act on the vascular bed, their effect on inflammatory lesions induced by intradermal injection of bradykinin and histamine was examined. Inflammatory lesions were evaluated by use of ¹²⁵I-guinea pig serum albumin. Guinea pigs received an intravenous injection of ¹²⁵I-albumin, followed immediately by intradermal injections (0.1 ml) of inflammatory agents using the dorso-lateral skin; doses were allocated to sites according to Latin squares to avoid bias resulting from site and animal variation. After a predetermined time animals were killed and skinned, and disks of skin which included the whole of the lesion were excised with a punch (16 mm diameter) for counting in a well-type γ spectrometer¹⁶. The ¹²⁵I-albumin in 1 μl of blood was also determined for each animal, to provide a reference.

Figure 1a shows the dose-response relationship between extravasated plasma albumin and the dose of intradermal bradykinin over a 30 min period. When PGE₁ (1 μg per dose) was mixed with bradykinin before injection, there was a marked shift of the dose-response curve to the left. The increase in slope of the shifted curve prohibits a potency ratio estimate, but at the level of response to 1 μg

Fig. 2 *a*, H (●), response to intradermal histamine (0.5 μg per 0.1 ml). H+PGE₁ (○), response to histamine (0.5 μg histamine per 0.1 ml) mixed with PGE₁ (doses as shown). □, Uninjected skin. Responses represent mean ¹²⁵I-albumin count in lesion/count in 1 μl blood (±95% confidence limit). *b*, △, Time course of inflammatory response produced by intradermal histamine (2.5 μg histamine per 0.1 ml) at arrow. ▲, Time course of the response to a mixture of histamine (2.5 μg) and PGE₁ (1.0 μg) per 0.1 ml.

of bradykinin the presence of PGE₁ at 1 μg per dose produced a nearly 100-fold increase in the potency of bradykinin. The dose-response relationship of intradermal PGE₁ alone (Fig. 1*b*) shows that the potentiation phenomenon is not simply caused by summation.

Potentiation was also observed when PGE₁ was mixed with histamine before intradermal injection. Potentiation increased with increasing doses of prostaglandin (Fig. 2*a*) and activity was apparent when PGE₁ was present at doses in the order of a few nanograms, indicating a functional significance for the phenomenon.

By a continuous recording technique involving the use of an external γ detector over a single lesion¹⁷, it was shown that potentiation was not accompanied by a substantial prolongation of the response (Fig. 2*b*).

Response potentiation was also observed in varying degrees when histamine or bradykinin was mixed with other prostaglandins (Table 1). In general, potentiation was greater with mixtures of bradykinin and prostaglandin than with mixtures of histamine and prostaglandin (with approximately equipotent doses of agonist). Response potentiation activity ranked PGE₁>PGE₂>PGA₁>PGF_{2α}. The addition of PGF_{2α} to histamine produced a reduction in response but this was not significant by the paired *t*-test, 0.5<*P*<0.2.

We wished to know whether a similar phenomenon might be observed in endogenous inflammatory reactions, where the nature of inflammatory mediators is uncertain and where prostaglandins might act either on the vascular bed itself or on adjacent cells, or at both levels. The effect of local injection of prostaglandins upon three defined allergic inflammatory reactions was therefore examined. Figure 3 shows potentiation by PGE₁ (1 ng–10 μg) of reactions of Type I (passive cutaneous anaphylaxis), Type III (reversed passive Arthus) and Type IV (delayed hypersensitivity) reactions. For Type I reactions, animals received intradermal injections

of skin-fixing antibody 4 h before intravenous injection of antigen, bovine γ-globulin (BGG) and ¹²⁵I-albumin, PGE₁ was injected into skin sites immediately before the intravenous injection and isotope accumulation in the lesion was determined over a 30 min period. For Type III reactions, animals received intradermal injections of antiserum followed 20 min later by an intravenous injection of antigen (BGG) and ¹²⁵I-albumin. PGE₁ was injected into sites immediately before the intravenous injection and isotope accumulation in the lesions determined over a 2 h period. For Type IV reactions, animals were given intradermal purified protein derivative of tuberculin (PPD) 5 weeks after Bacillus Calmette-Guérin (BCG) vaccination. Sixteen hours later animals received intradermal injection of PGE₁ into skin sites, followed immediately by intravenous injection of ¹²⁵I-albumin, isotope accumulation in the lesions being determined over a period of 2 h. Choice of pulse times in these experiments was based upon previous delineation of the time course of these reactions¹⁷.

Prostaglandins E₁, E₂, F_{2α} and A₁ are much less active than histamine or bradykinin at increasing vascular permeability (for example, 10 μg PGE₁ was 1,000–10,000 times less potent than bradykinin). Prostaglandins can, however, cause marked potentiation when injected with histamine and bradykinin, and they are also able to potentiate endogenous inflammatory reactions. In all these situations, potentiating activity could be observed with low concentrations (of the order of a few nanograms) of PGE₁.

Fig. 3 Effect of a range of doses of PGE₁ on: *a*, Type I reaction (passive cutaneous anaphylaxis); *b*, Type III reaction (reversed passive Arthus); *c*, Type IV reaction (delayed hypersensitivity). ○, Lesions injected with PGE₁ at the doses shown; ●, lesions injected with saline; □, uninjected normal skin. Responses represent mean ¹²⁵I-albumin count in lesion/count in 1 μl blood (±95% confidence limits).

The mechanism of the potentiation of inflammatory exudation induced by prostaglandins remains unestablished. The possibility that their action may depend on local vasodilatation raising the transmural hydrostatic pressure gradient has not been excluded. Parallels with other physiological systems suggest, however, that potentiation may be due either to sensitisation of agonist receptors on vascular endothelial cells,

or to modulation of cyclic AMP levels in endothelial cells through adenylyl cyclase. Similar mechanisms may control the release of mediators from cells adjacent to the vascular endothelium in the case of endogenous inflammatory reactions, involving mediators from mast cells (Type I reactions), polymorphonuclear leukocytes (Type III reactions), or lymphocytes and macrophages (Type IV reactions). In other species (rat and man) prostaglandins have been reported to increase vascular permeability by release of vasoactive amines from mast cells⁷. Clearly, potentiation activity would amplify inflammatory responses produced by release of vasoactive amines, so that the concept of prostaglandins merely acting as intermediates or 'trigger substances' in these species may represent an over-simplification.

We conclude that prostaglandins, by virtue of their activity as modulators of inflammatory responses, may have a major role in inflammatory mechanisms.

Prostaglandins, Aspirin-like Drugs and the Oedema of Inflammation

OUR discovery that aspirin-like drugs inhibit the biosynthesis of prostaglandins¹⁻³ led to the proposal that this was their main mechanism of action^{1,4}. Several observations have added force to the theory. These include the correlation between relative potencies as prostaglandin synthetase inhibitors *in vitro* and anti-inflammatory activity *in vivo*⁵⁻⁷, the generality of the inhibition in many species and preparations⁸, and the demonstration of release of prostaglandins in inflammation^{9,10} and fever^{11,12}. In addition, prostaglandins of the E series cause an inflammatory response in the skin of rats and man^{13,14} and a fever in cats^{15,16} and man¹⁷.

Prostaglandins cause increased vascular permeability in many species and their potency (on a weight basis) is equal

Fig. 1 Potentiation by PGE₁ of the rat paw swelling induced by bradykinin or histamine. The bars show the mean ($\pm$ s.e.m.) increase in paw volume (μ l) 30 min after injection of 0.1 ml saline (S), bradykinin (B), histamine (H), PGE₁ or mixtures as specified. The effects of saline alone are shaded across the figure to allow easier comparison of the added effects of the other substances. Numbers inside the bars refer to numbers of paws used. Note that addition of PGE₁ either to histamine or to bradykinin substantially increased the paw swelling, but addition of bradykinin to histamine did not.

to that of bradykinin and somewhat higher than that of 5-hydroxytryptamine (serotonin) and histamine¹⁸. The oedema induced by prostaglandins is not, however, dose-dependent as it is with bradykinin; indeed higher doses of prostaglandin E₁ (PGE₁) inhibit the oedema caused by other mediators¹⁹. Additive effects, rather than synergism, were also demonstrated between prostaglandins and histamine, bradykinin or carrageenin injections¹⁹.

We have shown that PGE₁ and PGE₂ sensitise the pain receptors to mechanical and chemical stimulation and suggested that the analgesic action of aspirin-like drugs could be explained by the abolition of the sensitisation caused by the local release of prostaglandins during an inflammatory reaction²⁰⁻²². The present experiments were designed to test whether a similar mechanism could account for the pro-inflammatory actions of prostaglandins. We have reinvestigated the interaction between prostaglandins and other putative mediators and carrageenin-induced oedema. Wistar rats of either sex weighing 150-250 g were used. In the first series of experiments, injections (0.1 ml) of different substances were given into the plantar region of the hind paws. Substances used included PGE₁ (0.5-5 μ g), bradykinin (1-5 μ g) and histamine (7-20 μ g); they were given either alone or in mixtures as specified later.

In the second series of experiments, carrageenin (2% w/v in saline) was injected into the hind paws to induce inflammation. All but the control animals were treated with indomethacin (20 mg kg⁻¹, 30 min beforehand in Tris buffer at pH 8). In the indomethacin-treated group, some rats received a mixture of carrageenin and either PGE₁ (0.1-0.5 μ g), PGE₂ (0.1-0.5 μ g), PGF_{2 α} (0.5 μ g), bradykinin (1 μ g) or histamine (20 μ g).

Injections were made into both hind paws in random order; the oedema was measured by the mercury displacement method²³.

Figure 1 summarises the results obtained by injecting inflammatory mediators into the rat paws. To facilitate comparison of the effects of the mediators, above the increased paw volume caused by saline alone, the saline effect has been shaded on the figure. There was a dose-dependent effect of

bradykinin but no significant increment ($P > 0.5$) to varying concentrations of histamine or PGE_1 . These results agree with those of Glenn¹⁹.

The histamine-bradykinin mixture produced an effect no greater than that of histamine alone. The effects caused by mixtures containing PGE_1 were, however, substantially greater for histamine and for bradykinin than those expected by simple addition. Increasing the dose of PGE_1 from 0.5 to 5 μg did not increase the potentiating activity.

Fig. 2 Potentiation by PGE_1 or PGE_2 of the rat paw swelling induced by carrageenin in the presence of indomethacin. Panel *a* shows the effects of carrageenin alone (CC) over a 3 h period. To facilitate comparison, the swelling induced by carrageenin in the presence of indomethacin (C) is shown as a shaded area in each panel. Prostaglandin E_1 (0.1 μg ; 0.1 $\text{E}_1 + \text{C}$) substantially increased the paw swelling induced by carrageenin, and 0.5 μg (0.5 $\text{E}_1 + \text{C}$) was even more effective. Panel *b* shows similar but smaller effects for PGE_2 but no effect with $\text{PGF}_{2\alpha}$. Panel *c* shows that 20 μg histamine (20 H + C) had a potentiating effect similar to that of 0.1 μg PGE_1 . Curves inside shaded areas in the three panels show the effects of PGE_1 (0.5 μg), PGE_2 (0.5 μg), $\text{PGF}_{2\alpha}$ (0.5 μg), histamine (20 μg), or saline (0.1 ml) given alone.

Figure 2 shows the effects of addition of various substances on the paw swelling induced by carrageenin. Panel *a* shows that indomethacin reduced the paw swelling induced by carrageenin alone. In order to test the effects of exogenous prostaglandins on the paw swelling induced by carrageenin, it was necessary to suppress endogenous prostaglandin formation by pretreatment of the rats with indomethacin. In these animals, PGE_1 , PGE_2 or $\text{PGF}_{2\alpha}$ (0.5 μg ; 5, 4 and 4 experiments respectively) caused no greater paw swelling at 30 min than did saline alone (8 experiments), but their effects lasted for a longer time. There was little or no difference between the paw swelling induced by the three prostaglandins at this dosage, but their effects on the oedema produced by carrageenin in the presence of indomethacin (shown as a shaded area on the graphs) varied substantially. Prostaglandin E_1 (0.1 μg , 5 experiments) potentiated the paw swelling at 30 min and at 0.5 μg (6 experiments) the effect was even greater. Prostaglandin E_2 (0.1 μg , 6 experiments; 0.5 μg , 9 experiments) was about one-fifth as potent as PGE_1 and $\text{PGF}_{2\alpha}$ (0.5 μg , 8 experiments) gave no potentiation. At the time (30–60 min) when the PGE_1 and PGE_2 were producing maximal potentiation of the carrageenin paw swelling they had no greater effect than saline when given by themselves. Histamine (20 μg , 8 experiments) gave some augmentation of the paw swelling induced by carrageenin in the presence of indomethacin but the effects were less than, or equal to, the potentiating action of PGE_1 at 0.1 μg , that is, it was at least 200 times weaker than PGE_1 . Bradykinin (1 μg , 5 experiments) had no potentiating effect on the carrageenin paw swelling.

These experiments support our hypothesis that prostaglandins E_1 and E_2 potentiate the oedema-producing capacity of other inflammatory mediators. Assay of mediators in inflammatory exudate produced by carrageenin in the rat showed release of both histamine and bradykinin in the early phase but that of PGE_2 only after two to three hours⁹. Thereafter the concentrations of $\text{PGF}_{2\alpha}$ and histamine increased

steadily and paralleled the time course of migration of polymorphonucleocytes into the site of injury²⁴. Our results, which show that indomethacin has an inhibitory effect on the carrageenin-induced oedema as early as 1 h after injection, are in agreement with those of other authors²⁵ and suggest that at the time when there is little or no migration of polymorphonucleocytes there is already a release of prostaglandin by the local cells and that this release potentiates the effects of the other mediators. Phagocytosis by polymorphonucleocytes also releases prostaglandins²⁶, so there could be a contribution to the potentiation from this source also. We propose therefore that the role of prostaglandins in the oedema of inflammation is to intensify the effects of the other chemical mediators. In this respect, their activity parallels that which we found for the pain of inflammation^{20–22}. Such an action explains why aspirin-like drugs only reduce but do not abolish the response to an inflammatory stimulus. For example, in this work and previously^{24,25,27}, the rat paw swelling induced by carrageenin was reduced by less than 60% by high doses of anti-inflammatory substances such as indomethacin.

We thank Miss Vera Pontieri for assistance and the Wellcome Trust, the Medical Research Council, and the University of Honduras for grants.

Incorporation of Rhodopsin Proteolipid into Bilayer Membranes

RHODOPSIN constitutes over 80% of the membrane-bound protein in the outer segment of rod photoreceptors^{1,2}. Absorption of light by rhodopsin leads to large changes in the ionic current of the receptor cell³: excitation of a single rhodopsin molecule transiently (~ 1 s) stops about 10^7 Na ions from flowing across the plasma membrane of the outer segment^{4,5}. The mechanism by which the excited rhodopsin molecule achieves such large reduction in ionic flux is not understood, partly because natural rhodopsin-containing membranes amenable to the experimental methods required to investigate the transport properties of rhodopsin have not been successfully prepared. As an alternative to natural membranes, attempts to form model membranes which incorporate the properties of the photoreceptor have been made. Takagi *et al.*⁶ and Fesenko *et al.*⁷ have reported the incorporation of ultrasonicated fragments of rod outer segments into model membranes. In this study we report the successful incorporation of native, purified rhodopsin into bilayer membranes. This should make possible the investigation of the mechanism by which rhodopsin molecules act in the rod photoreceptor.

Two recent advances have permitted us to incorporate rhodopsin into model membranes. One is the report by Hong and Hubbell⁸ on the preparation of detergent-free phospholipid vesicles containing purified rhodopsin. The other is the report by Montal and Mueller⁹ on the formation of lipid bilayers, in the absence of any organic solvent, by the hydrophobic apposition of lipid monolayers. In the method of Montal and Mueller monolayers of lipids dissolved in a readily volatile solvent are spread on an air-water interface in each of two compartments. The compartments are separated by a hydrophobic partition in which there is a small (about 0.25 mm diameter) aperture. After the solvent evaporates, a bilayer is formed by raising the water level in two compartments above the level of the aperture. The hydrocarbon tails of the lipids in the two monolayers oppose each other across the aperture forming the bilayer. To incorporate rhodopsin into these model membranes, therefore, it was first necessary to form lipid monolayers containing native, purified rhodopsin.

To extract rhodopsin, rod outer segments from dark-adapted bovine retinas (Hormel Co.) were isolated by sucrose flotation, and purified in a discontinuous sucrose gradient¹⁰. Phospholipid vesicles containing rhodopsin were prepared following the method of Hong and Hubbell⁸. Dodecyl trimethyl ammonium bromide (DTAB) (Eastman Co.) (100 mM) which had been recrystallised twice was used to extract rhodopsin. Phospholipid recombinants were made with chromatographically pure egg lecithin (General Biochemicals). Recombinants were made with three different molar ratios of lecithin to rhodopsin: 100:1, 50:1, and 25:1 assuming an extinction coefficient for rhodopsin of 40,600 at 498 nm (ref. 11). Unlike Hong and Hubbell we did not delipidate the rhodopsin-DTAB micelles before recombination with the phospholipid, so the total phospholipid to rhodopsin mol ratio must be larger than what we report here. The detergent was removed by exhaustive dialysis (4 d in the dark at 4° C) against 5 mM Tricine (Tris(hydroxymethyl)methyl glycine), pH 7.0. At the end of

Fig. 1 Difference spectrum of rhodopsin in hexane. The absorption spectrum was measured in a Cary 14 spectrophotometer with the use of a 1 cm path length cuvette in a temperature-regulated jacket (10° C). The spectrum shows a peak with $\lambda_{\max}$ at 498 nm.

the dialysis period the water-soluble rhodopsin lipoprotein vesicles were collected by centrifugation.

To form monolayers, the water-soluble rhodopsin lipoprotein must be extracted into an organic solvent and must not be denatured. In this study we attempted to extract rhodopsin lipoprotein into hexane by charge neutralisation with Ca, since it might be expected that ion-pair formation between Ca and the hydrophilic groups in the lipoprotein would enhance the solubility of the lipoprotein in solvents of low dielectric constant¹². Rhodopsin lipoprotein was dispersed in 4 ml of distilled water in a tube at concentrations of 0.25 and 0.5 mg ml⁻¹. One ml of hexane and 0.2 ml of a 100 mM CaCl₂ solution were added to the dispersion in rapid succession. The tube was vigorously mixed for 5 min and the two immiscible phases were then allowed to separate. Within 30 min more than 90% of the protein was extracted from the aqueous phase into the non-aqueous phase. Within 6 h the aqueous phase was completely clear indicating total lipid extraction. Extractions were routinely carried out in the dark at 4° C. Control experiments indicated, however, that extraction at room temperature was equally successful. After extraction the hexane phase had a characteristic red colour, was turbid and changed to a distinct yellow colour following illumination.

Absorption spectra in the visible range of the organic solvent phase showed a peak with $\lambda_{\max}$ at 498 nm (Fig. 1) which disappeared upon illumination. This result indicates that we succeeded in extracting native rhodopsin lipoprotein into hexane by ion-pair formation with Ca. We have thus formed a rhodopsin proteolipid, that is, a complex of lipid and protein which shares solubility properties with lipids¹³. Extraction of native rhodopsin was also successful with other organic solvents such as pentane and ether. Attempts to regenerate bleached rhodopsin in the organic solvent by addition of 11-*cis* retinal have failed so far.

In agreement with previously reported data on the extraction of cytochrome c into organic solvents¹⁴, we found that divalent cations (Ca, Mg) were more effective than monovalent cations (Na, K) in extracting rhodopsin into hexane.

and that Ca was more effective than Mg. The turbidity of the organic phase suggests that some water must have been extracted into hexane along with protein and lipid. We have not quantified the extent of water extraction. It is, however, expected that some water could have been extracted since rhodopsin is partially hydrophilic, as suggested by its amino acid composition¹⁵, the presence of carbohydrate residues covalently attached to it^{16,17}, and X-ray scattering data which indicate that rhodopsin in the photoreceptor membrane is partially surrounded by water¹⁸.

The rhodopsin proteolipid in hexane spreads into a monolayer when placed at an air-water interface. These monolayers could be used to form rhodopsin-containing bilayers following the method of Montal and Mueller. Monolayers were spread on a clean aqueous solution surface as condensed films at their own lens pressure. Bilayers were formed upon raising the solution level on both sides of the hydrophobic partition by injecting solution into the two compartments with syringes. We attempted at first to form symmetrical membranes by apposing two monolayers containing rhodopsin proteolipid. The membranes formed under these conditions were, however, extremely unstable. To increase stability we formed asymmetric membranes simply by apposing monolayers of different chemical composition¹⁹. One monolayer was formed with a mixture of glycerol dioleate (Arma Chemicals) and cholesterol (Sigma) dissolved in hexane, while the other was formed with the rhodopsin proteolipid.

Fig. 2 Membrane current in response to 20 mV voltage pulses across asymmetric bilayers. The upper trace in each record is current and the lower trace is voltage. Voltage pulses were repeatedly applied (5 per s) and the current traces were superposed on a storage oscilloscope. Asymmetric membranes were formed by apposition of two monolayers of different chemical composition. The records presented correspond to three different membranes. In all three membranes one monolayer was formed with a mixture of glycerol dioleate-cholesterol (1:0.26 molar ratio) dissolved in hexane, while the other monolayer was formed with either egg lecithin in hexane, or rhodopsin proteolipid in hexane or phospholipids extracted from bovine retinae (6 mg ml⁻¹) with chloroform:methanol (2:1 v/v) and purified in a silicic acid column. Rhodopsin-containing monolayers were formed with proteolipid extracted for at least 6 h from a 0.25 mg protein ml⁻¹ dispersion in water of either 50:1 or 25:1 lecithin:rhodopsin recombinants. All monolayers were spread over a 5 mM aqueous solution of Tricine, pH 7.0. All membranes were formed across the same aperture (6 × 10⁻⁴ cm²). The membrane capacitance measured by integration of the current records illustrated is: GDO-Chol/lecithin, 1.05 μF cm⁻²; GDO-Chol/rhodopsin proteolipid, 0.67 μF cm⁻²; GDO-Chol/retina phospholipids, 1.0 μF cm⁻².

The electrical properties of the membranes were studied under conditions of voltage clamp. Constant voltage pulses were repeatedly applied across the membrane, and the membrane current in response to these pulses was recorded. Membrane capacitance was determined by integration of the membrane current records according to the formula:

$$C = \frac{\int i dt}{V}$$

where C is membrane capacitance, i is membrane current and V is the magnitude of the applied voltage step. In Fig. 2 we present typical records. Analysis of these and other records is shown in Table 1. Asymmetric lipid bilayers made

with glycerol dioleate-cholesterol on one side and egg lecithin or phospholipids extracted from bovine retinas on the other side are indistinguishable from each other. They both have a capacitance of about 1 μF cm⁻² and a resistance of 10⁸–10⁹ Ω cm². These values are typical of membranes made with a variety of lipids in the absence of any organic solvent. In contrast, membranes made with glycerol dioleate-cholesterol on one side and rhodopsin proteolipid on the other have a distinctly smaller capacitance of only about 0.65 μF cm⁻². In the dark, the resistance of the rhodopsin-containing membrane is comparable to that of the unmodified membrane: 10⁸–10⁹ Ω cm². Thus, incorporation of rhodopsin in the dark does not affect membrane resistance, but does reduce membrane capacitance.

Table 1 Capacitance of Asymmetric Bilayer Membranes

Composition	Capacitance (μF cm ⁻²)	Dielectric thickness (Å) ‡
GDO-Chol*/lecithin	1.0 ± 0.1 (8) †	19
GDO-Chol/retina phospholipids	1.0 ± 0.1 (8) †	19
GDO-Chol/rhodopsin proteolipid	0.65 ± 0.08 (8)	29

* Glycerol dioleate: cholesterol (1:0.26 molar ratio).

† Average ± s.d. (number of measurements).

‡ Assuming ε = 2.1 (hexadecane) inside the membrane.

The change in membrane capacitance on incorporation of rhodopsin can arise from changes in dielectric constant, dielectric thickness or both. Careful measurement of the dielectric constant of both the unmodified and the rhodopsin-containing membranes is needed before a complete explanation can be given for the change in membrane capacitance. It is clear, however, that incorporation of a partially hydrophilic protein into a membrane would, if anything, increase the dielectric constant thus increasing the membrane capacitance with respect to that of an unmodified membrane²⁰. Therefore, if we assume that the dielectric constant does not change upon incorporation of rhodopsin, we can calculate a lower boundary for the effective dielectric thickness of the rhodopsin-containing membrane using the expression:

$$l = \epsilon A / 4\pi C$$

where C is membrane capacitance, A is area, ϵ is the dielectric constant and l is the effective dielectric thickness. Estimating 2.1, the dielectric constant of a long chained hydrocarbon, to be the dielectric constant of both the modified and the unmodified membranes, the dielectric thickness of a lipid membrane is 19 Å and the dielectric thickness of the rhodopsin-containing membrane can be no smaller than 29 Å. The hydrocarbon region of the rhodopsin-containing membrane in rods is 28 Å thick^{21,22}. The rapid rotational motion of rhodopsin in the photoreceptor membrane has led Cone²³ to propose that rhodopsin might act as a light-activated diffusional carrier which transports Ca ions by tumbling across the hydrophobic region of the membrane. The fact that the hydrocarbon region of the rhodopsin-containing membrane is thin suggests an alternative mode of action for rhodopsin as a diffusional carrier which does not require the thermodynamically improbable tumbling of a partially hydrophilic glycoprotein into a hydrophobic phase. If excitation of rhodopsin exposes Ca binding sites which are not available in the dark, then the charge neutralisation which might result from ion-pair formation with Ca would allow rhodopsin to sink deeper into the hydrocarbon region of the membrane, much in the way that Ca permits extraction of rhodopsin into hexane as reported here. In the thin hydrocarbon region of the photoreceptor membrane (~28 Å) the large (~45 Å diameter²⁴) rhodopsin molecule need only sink a few Å to cross the low dielectric region. Thus, rhodopsin might translocate Ca ions across the membrane not by

tumbling, but rather by bobbing in the membrane. Indeed, Blasie¹⁸ has interpreted the changes in X-ray scattering by the photoreceptor membrane that follow illumination as resulting from rhodopsin molecules sinking by about 10 Å into the hydrophobic region of the membrane.

The rhodopsin-containing model membranes have so far been short-lived, with an average lifetime of only about 1 min, making the search for light effects difficult. We have, however, investigated the effects of bright flash illumination on the capacitance of these membranes, and have not distinguished any effects within the resolution of our method. Future investigation will pursue the effects of light on the transport properties of rhodopsin in these model membranes.

We thank M. Hall for helpful discussions, S. Hagiwara for encouragement and support, and P. K. Brown for his gift of 11-*cis* retinal.

Fate of Bacteriophage Lambda in Non-immune Germ-free Mice

THE clearance of colloidal particles in animals has been studied in several experiments¹⁻¹⁰. The use of bacteriophage in such studies offers a sensitive tool to augment materials such as dyes, radioactive colloids and enzymes for analysing mechanisms of handling foreign particulate material. Furthermore, such use of bacterial viruses may enhance the general under-

Studies of the intracellular distribution of phages ϕ X174 and T2 in the organs of rabbits and guinea pigs demonstrated that when they were taken up by the cells of the reticuloendothelial system (RES), most plaque-forming units (PFU) became localised in the larger granular fraction (lysosomes and mitochondria) of the cells². Inchley *et al.* studied the response of mouse macrophages to injected phage T4^{11,15,17}, finding that within 30 min of ¹²⁵I-T4 injection, more than 99% of the phage was phagocytosed by liver Kupffer cells. Inchley also found that T4 PFU could be recovered from the spleen 5 d after the initial injection¹¹. Extensive studies have shown that elimination of colloidal particles is exponential with time regardless of whether these particles were phage^{11,15,17}, animal viruses¹⁸ or inert substances^{1,19}.

Our studies of the fate of phage λ , injected by several routes into NIH germ-free mice, differ from previous studies in several ways. First, previous investigations focused on elimination of foreign particles, either by phagocytosis or by antibody formation, while we were interested in the distribution of phage which survive rapid elimination. Second, most studies have used isotopic label to determine the location of the injected particles without showing whether the particles retained their biological activity, while we assayed for the ability to make plaques. Third, previous investigations concerned tissues known to be involved in the RES, while we were interested in any tissue accumulating phage. Fourth, our phage could be distinguished from possible contaminants by its genetic markers (Table 1). Fifth, the use of germ-free animals precluded interactions with microorganisms in the gastrointestinal tract, although the germ-free mouse system is not an ideally "clean" system for experimental purposes, for leukaemia viruses and other virus-like particles have been found in the thymus glands of such mice²¹⁻²⁴.

Table 1 Pattern of Test Results by which λ pgal₈₅₇CI857 (ref. 20) can be distinguished from Possible Contaminating Phage

Phage	Plaques on pm+ host	Plaques on pm- host	Plaques at 34° C	Plaques at 40° C	Plaques on λ lysogen	Red plaques on MacConkey's gal with gal- host
λ pgal ₈₅₇ CI857	+	-	Turbid	Clear	-	+
Wild type λ	+	+	Turbid	Turbid	-	-
Wild type or virulent phage	+	+	Clear	Clear	+	-

The phage were checked periodically for their ability to transduce the galactose operon, for the presence of CI857 (production of a heat-sensitive repressor) as manifested by clear plaques at 40° C and turbid plaques at 34° C, and for sensitivity to λ immunity as demonstrated by the inability of the phage to plate on a *su*₁₁₁⁺ λ lysogen.

Figure 1 shows that the gross distribution of the virus was tissue-specific, regardless of the injection route. This, however, was not true with force-feeding, which failed to introduce significant amounts of virus to any tissues and spaces examined. Little, if any, virus was detected in the faeces after injection intraperitoneally, intramuscularly, intravenously or *per os*.

By 3 h after infection the blood contained considerably more virus than the peritoneal fluid even if the virus were given intraperitoneally. Within 48 h the virus was cleared from the blood (<10 PFU ml⁻¹) and the peritoneum, no matter where the virus was introduced.

All the organs examined in the infected animals contained viable phage. Of these organs, the spleen had the highest titre. With increasing time, the titre of phage within the liver decreased rapidly. The results were similar with the thymus. Within 3 h after intraperitoneal, intramuscular, and intravenous administration of virus the titre of virus in the spleen in PFU g⁻¹ of

after infection, the blood titre had decreased to zero while the spleen titre still exceeded 10^4 PFU. This difference between the spleen and other organs increased with time.

The titres of phage found in any of the organs and in the two body spaces analysed were higher if the phage were injected intraperitoneally. This might indicate that the phage within the

Fig. 1 Plot of the number of PFU g^{-1} wet tissue detected in: blood ($\odot$); peritoneum ($\diamond$); spleen ($\times$); liver ($\square$); thymus ($\otimes$); and kidney (γ); as a function of time after injection of phage by several routes: intraperitoneal (a); intramuscular (b); intravenous (c), and per os (d). λ *pgal*₈₅, CI857, grown vegetatively on *E. coli* C600 (ref. 25), was purified using a CsCl gradient²⁶. NIH albino germ-free mice of mixed sexes were maintained in a plastic Trexler-type isolator unit provided by the Laboratory Aids Branch at NIH²⁷⁻³⁰. Sterility checks were made by streaking samples of organs, faeces, urine and blood onto Tryptone B1 plates to demonstrate the absence of bacteria and by titrating the samples against several strains of *E. coli* to demonstrate the absence of coliphage. All experiments with the germ-free animals were done within the isolator, and not with animals removed from the gnotobiotic environment. All materials passed into the isolator through an air-lock were either autoclaved for 20 min at 121°C, or swabbed with peracetic acid. The acid destroyed the coliphage used in these experiments. 2×10^{12} PFU of *E. coli* phage λ *pgal*₈₅, CI857 were injected intramuscularly, intravenously, intraperitoneally or per os. Phage samples in 0.2 ml phosphate-buffered saline (PBS) containing 0.01 M $MgSO_4$ were injected intravenously into the tail vein or intramuscularly into the quadriceps femoris muscle group. The intraperitoneal injections of phage in 0.5 ml PBS were given in the right middle quadrant, caudal to the liver. A mouse restrainer (Fisher) was used to facilitate injection procedures. A polyethylene tube 0.03 inch in diameter, forced down the oesophagus, was used to force-feed the phage sample in 0.2 ml PBS. At 3, 6, 24, 48 and 96 h after injection, mice from each injection group were anaesthetised with ether, the common carotids and jugular veins were cut and the blood was collected in a small test tube. The animals were pinned to a wooden board within the isolator and 3 ml of PBS was injected into the peritoneal cavity. After 1-2 min, the cavity was physically massaged and 0.5-1.5 ml of fluid was withdrawn. Faecal samples were collected when available. The animals were then dissected to remove the spleen, one kidney, the left lobe of the liver and (usually) the left lobe of the thymus. Each of the organs was washed thoroughly with PBS, and final washings were saved and titred to demonstrate that there was little or no phage remaining on the surface of the organs. This indicated that the virus was firmly associated with the organ samples and was not virus from the peritoneal fluid that had coated the organ. All samples were passed out of the isolator for further analysis. A 0.5 ml sample of PBS was added to each organ which was then ground with a sterile sintered glass pestle. Faecal samples were treated in the same way. The samples were titred against DB1 using an agar overlay method³¹. The presence of con-

peritoneal cavity were taken up preferentially by the liver and then the spleen, whereas phage injected intramuscularly or intravenously were distributed more uniformly. This agrees with earlier findings³² that compounds administered intraperitoneally are taken up by the portal circulation. Thus the liver maintains the highest concentration of injected substances. Particles injected intramuscularly and subcutaneously were distributed by the heart; because 28% of the cardiac output reaches the liver, the liver should have theoretically fewer particles within its substance when injected by other than the intraperitoneal route. Our results were similar. Therefore the effects, the metabolism and the excretion of phage might be different when injected by varied routes, for varying percentages of injected phage came into contact with the liver.

The spleen retained high titres of injected intact phage (10^5) for prolonged periods of up to 7 d. Inchley also found intact phage in the spleen up to 5 d after infection³³.

Retention of phage in the spleen was previously suggested to be due to the fact that "inactivation of antigen occurs much more rapidly within Kupffer cells than within splenic macrophages"³⁴. This interpretation predicted that the spleen, well-endowed with macrophages, would retain lower titres of phage than other tissues deficient in macrophages, such as the kidney. Our data (Fig. 1) suggested an alternative interpretation that the spleen was engaged in non-destructive capture of antigens. The spleen can carry out phagocytosis, but recently a non-phagocytic capturing method utilizing the Schweigger-Seidel capillary sheaths was described³⁵. This latter mechanism might be responsible for the non-destructive capture of phage that we observed. This ability to non-destructively retain antigen might allow the spleen to serve as a continued source of antigen for the stimulation of antibody formation.

Although it was suggested that non-phagocytic antigen capture by the Schweigger-Seidel reticulum cells required interaction with antibody³⁶, in our experiments such an interaction was remote, for we were unable to detect neutralising antibody to λ ($K < 10^{-3}$)³¹.

Antigen trapping in the spleen may be closely coupled to antibody formation. An intact spleen is necessary for maximal antibody response³⁷. The removal of the spleen severely depresses the antibody response in mice, and this defect in antibody formation following splenectomy cannot be corrected by injection of splenic elements³⁷. Furthermore, in neonatal rats and mice the spleen is an alymphoid organ^{3,4}. The ability to trap antigen appears 2 weeks after birth^{3,4}. Multiple injections of antigen are required during this first 2-week period to stimulate antibody formation, whereas no single injection during this time produces an antibody response⁴. Following the development of the lymphoid elements in the spleen a single injection of antigen stimulates formation of antibodies. These observations indicate that the structural integrity of the spleen might allow cell-to-antigen and cell-to-cell interaction for antibody formation^{2,5,8,19-25,34-39}.

The rapid elimination of phage in intact animals may explain the limited success of phage treatment of infectious diseases⁴⁰ and may interfere with attempts to observe prokaryotic viral gene expression^{41,42} in whole animals. This rapid rate of elimination may be slowed by overwhelming the RES with inert colloidal particles such as Thorotrast (thorium dioxide)^{19,43}.

We thank Dr George A. Hutchinson (Division of Computer Research and Technology, Laboratory of Applied Studies, NIH, Bethesda) for help with computer processing and Walter Wasser (Yeshiva University, New York) and Howard Bohner (Germ-free Animal Unit, NIH) for technical assistance.

osmotica in the ratio of 1:4 to give the final concentrations of enzymes shown in Table 1, and incubated at 28° C in the dark.

The arrangement of microspores in a few tetrads of *D. metel* (about 5%) was isobilateral but the predominant organisation was tetrahedral. Initially, the four microspores within the massive enveloping wall of the tetrad (Fig. 1a) were naked, but they subsequently developed thin cellulose walls, at which stage they could easily be released from the envelope by gentle pressure. Conventional methods were then used to obtain free protoplasts. The cell walls of both immature and mature pollen grains were resistant to the enzymes used in this study. The mature pollen grains germinated readily and the pollen tubes were then susceptible to enzyme action. Their contents, however, were released as sub-protoplast fragments and not as entities.

Nuclear Divisions in Protoplasts isolated from Pollen Tetrads of *Datura metel*

THE significance of haploid protoplast research has been discussed by Bhojwani and Cocking¹. They have succeeded in isolating protoplasts from microspores and bringing about regeneration of cell walls. The occurrence of nuclear divisions in protoplasts isolated from pollen tetrads of *Datura metel* L., a plant in which androgenesis could be experimentally induced^{2,3}, is described here.

Anthers from several buds were pooled in three groups, each of which contained either pollen tetrads, immature microspores or mature pollen grains. Segments of about 5 mm were excised from the central region of anthers and their contents gently squeezed out into 10% sucrose solution. The suspension volume for each group containing an entirely homogeneous cell population was adjusted to about 25×10^4 cells ml⁻¹. Enzymes were prepared as stock solutions in 0.05 M potassium acetate buffer, pH 5.4, containing 10% sucrose. The cell suspensions were mixed with the enzymes

Protoplasts from pollen tetrads were isolated in twenty-one of twenty-four enzyme-osmotica tested. Mixtures containing a cellulase (irrespective of its origin) or snail digestive juice (helicase) were effective, but pectinase and hemicellulase were ineffective (Table 1). The release of protoplasts in osmotica containing only cellulase (used as controls) was unexpected and contrary to earlier findings¹. This could not have resulted if callose (which is resistant to cellulase) were the only constituent of the tetrad wall. The snail enzyme complex which contains β -1,3- and β -1,4-glucan glucanohydrolases that degrade callose and cellulose, respectively, was comparable in its action with that of cellulase. Cellulase in conjunction with helicase, however, accelerated the rate at which protoplasts were released. The final yield was also higher. Similar observations have been recorded for *Atropa belladonna*, *Lycopersicon esculentum* and *Solanum xanthocarpum* (unpublished data). These findings suggested that the tetrad walls of *D. metel*, and possibly those of the others, contained cellulose in addition to callose. Lysis of either

disorganisation and consequent release of protoplasts. The enhanced activity observed with cellulase-helicase mixtures could be due to the complementary and simultaneous action of the enzymes at different sites. That the cell wall composition in the Solanaceae could be species and tissue dependent is further borne out by experiments with somatic cells. Raj and Herr obtained protoplasts from *Lycopersicon*⁴ and *Solanum*⁵ with polygalacturonase, an enzyme that was ineffective in the isolation of protoplasts from *Nicotiana* cells.

The average yield of protoplasts from tobacco tetrads was 35% (ref. 1). In our experiments, the highest percentages obtained were: 29.6 in 1 h, 48.3 in 2 h, 75.4 in 4 h, and 98.4 in 6 h of incubation. The isolated pollen protoplasts were spherical, non-vacuolate and of uniform size, about 10–12 μm in diameter (Fig. 1c). They contained dense cytoplasm and a prominent nucleus (Fig. 1b). Phenomena such as spontaneous aggregation, sub-protoplast formation and budding that are normally associated with somatic protoplasts⁶ were, however, not observed.

The protoplasts were cultured as hanging drops in a modified White's medium. The nucleus in some of the

5 d of incubation, producing three nuclei unaccompanied by cell wall formation (Fig. 1d). One of the nuclei was larger than the other two (Fig. 1e), a condition analogous to the male gametophyte *in vivo* which contains a larger vegetative and two smaller sperm nuclei.

I thank Dr P. S. Rao for a gift of cellulase Onozuka and Dr T. S. Rangan for discussions.

The Secretion of Migration Inhibitory Factor by Intact Schistosome Egg Granulomas maintained *in vitro*

TUBERCLE formation and delayed type dermal reactivity are the hallmarks of tuberculosis, yet the relationship between the two has only recently begun to be elucidated. Most experts still believe that the tuberculous granuloma is a tissue response to the irritative effect of mycobacterial lipids^{1,2}. While the strength of this concept made it difficult to establish granulomatous inflammation as a host immunologic response^{3,5} Warren *et al.*⁶ showed that the schistosome egg granuloma is a manifestation of delayed hypersensitivity, as demonstrated by anamnestic reactivity, specificity, and transferability with immune lymphoid cells but not with antiserum. It was subsequently correlated with other parameters of the cell-mediated immune reaction, including delayed dermal reaction, lymphocyte transformation and macrophage-migration inhibition⁷. Similar results have been provided for the experimental tuberculous granuloma^{8–13}. Here we report the secretion of a lymphokine by intact granulomas maintained *in vitro*, further confirming the hypersensitivity character of the schistosome egg granuloma.

Intact granulomas were isolated¹⁴ from the livers of Swiss mice (Carworth, CF1 strain) exposed 8 weeks previously to 200 cercariae of the Puerto Rican strain of *S. mansoni*. Granulomas were washed twice with 150 ml of saline and settled in a conical flask. One hundred granulomas were counted into plastic 35 $\times$ 10 mm Petri dishes, No. 3001 (Falcon Plastics, California) and were suspended in 1.9 ml of RPMI-1640 medium (Grand Island Biological Company, NY) supplemented with 10% heat-inactivated normal human plasma, 100 units ml⁻¹ of penicillin, 100 μg ml⁻¹ of streptomycin and 2 mmol ml⁻¹ of glutamine. Soluble egg antigens (SEA) were obtained from homogenised parasite eggs as described earlier¹⁵. The protein content of this preparation was 470 μg ml⁻¹ (ref. 16). For the examination of non-specific reactivity either a mycobacterial culture filtrate (a 10-fold concentrate of *Mycobacterium tuberculosis* strain H₃₇Ra (ref. 17) having a protein content of 5 mg ml⁻¹) or commercial PPD, second strength (Parke-Davis and Co., Detroit, Michigan) was used. Dishes were set up in duplicate or triplicate for each antigen concentration and buffer controls. Supernatants from each concentration of antigen

macrophage migration inhibition using the indirect assay of David¹⁸. Peritoneal exudate cells were obtained from 400 g female Hartley strain guinea pigs after 2 d irritation with Klearol, a light mineral oil. The assay was carried out as described earlier⁷. One-half ml volumes of culture fluids were mixed with the same volume of medium and added to duplicate capillaries in the migration chambers. Preliminary testing of the culture supernatants obtained after the first 24 h of incubation gave erratic and mainly negative results. Results obtained from 48-h supernatants are shown in Fig. 1. Assaying the supernatants has the additional advantage of having minimal residues of human plasma and antigen. Percentage of inhibition was calculated as follows:

$$\% \text{ Inhibition} = \frac{100 - \frac{\text{Average migration of normal cells in supernatants of antigen-stimulated granulomas}}{\text{Average migration of normal cells in supernatants of unstimulated granulomas}} \times 100}{100}$$

Twenty per cent or greater inhibition was considered to be significant.

Fig. 1 The inhibition of migration of normal guinea pig peritoneal cells by supernatants from liver granulomas maintained *in vitro*. SEA, Soluble schistosome egg antigens; MCF, mycobacterial culture filtrate; PPD, purified protein derivative.

The isolated granulomas were well circumscribed, compact entities containing one or occasionally more parasite eggs surrounded by fibroblasts, macrophages, occasional epithelioid cells and eosinophils encased in a fibrous matrix. Numerous lymphocytes were visible at the periphery of the lesions, but no plasma cells were seen (Fig. 2). Supernatants obtained from cultures of unstimulated granulomas did not inhibit migration of normal peritoneal cells. SEA up to 40 µg per migration chamber was not inhibitory to the migration of normal peritoneal exudate cells, but both mycobacterial culture filtrates and PPD caused strong (30–50%) inhibition of the migration of cells when added in the concentration of 10 µg per chamber. Thus, the occasional higher inhibitory values of migration seen in PPD or mycobacterial culture filtrate-incubated cultures may be due to the direct inhibitory action of the residual antigens on normal peritoneal exudate cells.

Pooled percentages of migration inhibition showed that incubation of granulomas with 0.1 µg of SEA yielded five of nine supernatants which significantly inhibited the migration of macrophages (mean 20.3 ± 4.7%). Optimal inhibition (nine of nine) was obtained from 1 µg SEA incubated samples (mean 42.4 ± 6.2%) while 10 µg antigen stimulated MIF production in only one of seven samples (mean 8.9 ± 6.4%)

Fig. 2 a, Sections of liver granulomas from mice infected with *Schistosoma mansoni* for 8 weeks. Note schistosome eggs in the centre of several of the lesions. Haematoxylin and eosin × 96. b, High magnification of one of the more highly cellular granulomas, showing predominantly mononuclear cell composition. Haematoxylin and eosin × 384.

Reactions of delayed hypersensitivity are considered to be mediated by a number of soluble substances known as lymphokines^{19,20}. Lymphokines obtained from tissue cultures of antigen-stimulated lymphocytes were shown to elicit inflammatory reactions in normal animals when injected intradermally^{19,21,22}. Recently, extracts of delayed hypersensitivity skin reaction sites were found to possess chemotactic but not MIF activity for macrophages and were shown

animals²³. No information is available, however, on the role of lymphokines in inflammatory reactions such as the granuloma.

The granulomatous inflammation around injected schistosome eggs in the lungs of mice is a delayed hypersensitivity immune response⁶. Also, hypersensitivity-type granulomas have been elicited in mycobacterium²⁴, histoplasma- or schistosome-infected animals¹² following the injection of bentonite particles coated with soluble antigens of these organisms, while bare or heterologously-coated particles evoked small foreign body type granulomas. Using this model it was also shown that infected mice, which otherwise reacted with a foreign body granulomatous inflammation around bare particles, developed florid hypersensitivity type granulomas when systemically challenged with the homologous soluble antigen¹². It was surmised that such a reaction could have been caused by the action of circulating lymphokines liberated by the interaction of antigen and the sensitised system. This was shown recently when a large systemic challenge dose of old tuberculin elicited the appearance of MIF and interferon in the circulation of BCG-infected mice²⁵.

While it has been speculated that mediators such as MIF may be instrumental in the formation of the infectious granuloma^{9,26,27} our results provide the first evidence that the granuloma is an immunologic entity capable of secreting soluble mediators on antigenic stimulation. Preliminary observations using concentrated MIF-rich culture fluids coated onto bentonite particles have revealed that MIF can directly elicit a mononuclear granulomatous response.

GENERAL

Ignorance about Limitations to Growth

Forrester¹ and Meadows *et al.*² have presented a family of computer models simulating the future behaviour of some world problems which suggest predicaments of mankind caused by compounded growth. Here I report preliminary results from a different pattern of models which imply that more hopeful outcomes are possible. Both models are assailable oversimplifications.

Proposing a different family of models is not intended as a rejection of the predicament position; indeed, for the present purpose of a broad discussions of assumptions, the predicament models would have to be invented if they did not already exist. The vital policy issues of the next few decades require the clearest illumination of alternatives that critical debate can provide, and in this spirit I regret Gabor's view³: "I hope and I believe that these critics will become silent in time for humanity to avoid the danger of perpetual poverty." I also dissent from Gabor's statement that the computer "can stimulate almost every system if we feed the data into it. It is superior to the human mind only in its ability to deal with complexity." The data have to be selected by the use of assumptions, as discussed below.

The Forrester-Meadows models contain five principal variables (population, food, capital, natural resources and pollution), the state of which is taken to represent the physical aspects of life in this world. This is a serious oversimplification, shared by all fruitful models and theories. Relations are set up between these variables, and the models consist of the growth rates, their multiplication and addition to exert effects on chosen points of the network of connections, and delays between original events and their consequences. Altogether, more than fifty items (computer statements) are used in ref. 1, more than 100 in ref. 2. The number of connections chosen in the process of modelling is larger still, and the assignment of quantities to each relation represents further choices. A description indicating why some connections are not made would require accounts of greater length. ("World III", for example, is chosen from over 7¹⁵⁰ networks formally consistent with the set of items in ref. 2.)

A typical example is shown in Fig. 1. Population increases by those born and decreases by those who died. If enough food is available, birth rate increases and death rate decreases. If, under the pressure of population growth, food production lags behind food requirements, the birth rate decreases and the death rate increases. As people once born die after a delay, (life expectancy), adequate food may "drive" the population to numbers prone to starvation ("overshoot" in control engineering terms), high death rate and severe decrease one to two generations later. This "collapse mode" occurs in all but a few highly "planned" sets of conditions (far from "normal" or "free running" or "intuitively corrected" conditions^{1,2}).

Similar "loops" to that of Fig. 1 connect crowding, pollution and the exhaustion of natural resources to "adjust the population to the maximum that food can support". This statement

of the inexhaustible set of the more detailed and technical assumptions in this model family:

(1) "The Malthusian thesis: . . . population is regulated to the food supply" (ref. 1, p. 27) and "the apparent goal of the world system is to produce more people with more (food, material goods, clean air and water) for each person" (ref. 2, p. 86).

(2) No regulatory mechanisms anticipate the Malthusian disaster—hence the predicaments.

Analogous assumptions are made about mounting world use of materials, pollution and crowding to the point of distress. Because both world history, demographic science, economics and the emerging concern for pollution and crowding are rich in varieties of theories, observations, conclusions and opinions, authorities can be found to support almost any assumption.

Fig. 1 Negative feedback in population control—after Forrester¹. Malthusian control: "negative loops that adjust population to the maximum that food can support".

No claims were made that refs 1 and 2 forecast world behaviour, or that they have been adequately refined. Yet disturbing implications are drawn from the model behaviour, and offered as cause for world, and decision makers', concerns and future actions.

In addition to the school of neo-Malthusians among demographers prepared to theorise on mechanisms of, and future trends in, population (seemingly a minority of all demographers), there exists another school which emphasises "demographic regulation" and "demographic transition". For the work described here, my chief source has been Bogue⁴; unless a specific reference is given all demographic information has been taken from his work. Errors of selection and interpretation are, of course, my responsibility.

The notion of demographic regulation implies that, in the past (and therefore possibly or probably in the future), adaptation has produced (and, it is hoped, will again produce) conditions of population stability in which a large part (sometimes almost all) of mankind was free from hunger without reacting with rapid population growth. Again, as in the Malthusian thesis, examples abound without being conclusive. (Samoa, the experience of many but not all developed countries to the 30's of this century, etc.) They are reinforced by partial evidence (or conjectures) arising from very early human pre-history, and much evidence from the animal world⁵. Demographic transition implies that such decreases in death rate as are almost world wide are followed, within one to three generations, by corresponding declines in birth rates, bringing population growth back to "manageable" levels.

doubling times of seventy to several hundreds of years. This set of theories has as many critics as the neo-Malthusian theories, and I use it as an undefended assumption. Clearly this pair of notions implies the exact opposite of assumptions 1 and 2 above.

Analogous assumptions are made about natural resources use and pollution: that, early enough, learning of recycling and substitution will forestall disaster in the natural resource sector, and that similar learning rates will rescue us from choking in pollution (pollution is also almost discounted in ref. 2).

Again, I do not defend these assumptions. I merely point out that some of today's key natural resources were not used 100 yr ago, and that many key resources of 100 yr ago have lost this status, such as charcoal, wood as fuel or ship-building material, and horses for transport in developed countries. Such substitution is likely to continue.

The most frightening dangers from pollution arise from uncertainty, as in the DDT chain of effects. With less than 1 part in 1,000 of past production of this pesticide yet active in the biosphere, many sudden bio-ecological disasters have occurred¹⁸. But I refuse to attempt a model of sheer uncertainty for policy guidance.

A further assumption is that of saturation of demand for any specific good per person, accompanied by gradual increase in productivity in developing conditions. This is consistent with refs 7 and 8 and much else since Engel's law of a 100 yr ago. It implies that, at some stage of development, labour is displaced to more and more "advanced" sectors of an economy, according to its taste for each tradeoff, progressively remote from primary needs. This is not unlike references^{1,2} to "global equilibrium", though built into the model at the beginning.

Finally, I assume that the use of this model will be for decision makers concerned to investigate if, from any given starting position (whether now or later) there is at least one feasible path to avoid any condition they define as "disaster". If a broad enough range of feasible paths exists (I believe that, as yet, this seems to be the case) much latitude for choice (in local jurisdictions) still exists, and can be optimised locally. Where possible, I prefer simple local models for ready aggregation to those requiring central decisions.

Having chosen a different school of demography as a source for key assumptions, as I turn to data I face the question how, in this age of science, such diversity of theories can co-exist. Data outside the developed countries before the Second World War are uncertain, and even fairly short term projections were wrong for England and Wales⁹. Population estimates for AD 2000 made in the 1920s have been overtaken and increased to around three to four times the original. Particularly for the large population masses of India and China, the cautions of refs 9 and 10 apply in full, and the comments in ref. 11 are surely optimistic.

Thus demographers have reserved the use of their most refined methods for comparisons between different countries at the same time or over the very short period (1950–1970) for which consistent data can be claimed^{4,5,8,12–14}. Transition models have emerged from some of these studies, but⁴ until the 1980 group of census data is available, no empirical resolution of the transition issue is possible. Even more, firm assignment of causes to population growth patterns seems entirely speculative. I discuss the uses made of these imperfect data on the basis of Fig. 2.

In Fig. 2a, approximate plots are shown for the vital statistics (crude birth and death rates) of France, Japan and Taiwan—the last two with speculative estimates from 1970 to about 2050. Both the fall of death rates (by now essentially world wide) and of birth rates (where it has occurred—and that, compared to biological capacity, has been argued to be almost global) have been more rapid the more recent the observation. Yet this speed-up is more conspicuous for death rates as well as

Malthusian mechanisms at work in the underdeveloped world, though very fast growth is occurring at present.

Birth and death rates in Europe at the time of Rome were each about 42 per 1,000. For stable populations, a lower death rate could lead to much higher growth rates than seem to have occurred before "transitions" (doubling times over 1,000 yr) except for short periods, locally. Higher birth rates were inconsistent with data but also biologically improbable because of the short fertility span of women. Lower birth rates would have led either to rapid extinction or, if reversed by corresponding increases in average food supplies or health, to a regain of the earlier values. Thus the "Malthusian trap" seems to have been homeostatic, except for fluctuations due to plague and drought.

Fig. 2 History of population growth rates in transition: from data to model. —, Deaths; — · —, births; 1, France; 2, Japan; 3, Taiwan. *a*, Data on growth rates (shaded areas) from France to Taiwan; *b*, Fermi function for *a*; *c*, Fermi function and its parameters for growth rate and constant death rate. 4, Bogue's projection 1970–2000; 5, UN projection 1970–2000; B, sample birth rate model.

In Fig. 2*b* I show how each of these patterns of vital statistics has been idealised for computation. In spite of the higher rates of change of the crude vital rates, the birth rate fall seems increasingly delayed, from 20 yr average in France, to 35 yr in Japan, to 50 yr in Taiwan. This is chiefly an artefact of selection of the three "prototypes": the inclusion of the European average¹⁴ would have shown 60 to 70 yr, but its overlap with Japan would have obscured the figure. The principal simplification is the omission of the "undershoot" of death rates. The raw data for Taiwan, for example, have death rates of about 6 to 7 per 1,000 since 1963. For a stable population, this requires a life expectancy of 150 yr. For modelling, this transition phenomenon was incorporated in the difference between rates. This implies that the modelled death rates are close to "intrinsic" death rates, but that growth rates are kept "crude". The modelled "birth" rates have no close demographic equivalent.

Each of the curves in Fig. 2*b* is of the form

$$\begin{aligned} \text{CBR}_\tau &= (B_0 - 15) (1 - 1/2 \exp [(\tau - \tau_0)/\tau_c]) \\ &\quad \text{for } \tau \leq \tau_0 \\ \text{CBR}_\tau &= (B_0 - 15) (1/2 \exp [-(\tau - \tau_0)/\tau_c]) \\ &\quad \text{for } \tau \geq \tau_0 \end{aligned} \quad (1)$$

where B_0 is the initial birth rate, τ_0 the date of the inflection, τ_c the time constant.

This is similar in values to the more familiar "logistic" curve, but simpler to compute, and easy to adapt if the particular situation appears to require an unsymmetrical decay, by adding one more to the three parameters required. I show the final model simplification in Fig. 2*c* where the death rate has been eliminated. Fig. 2*c* is a direct model of the population growth rate, and its relation to the empirical vital rates is obscured—yet not to the extent of the uncertainty of predicting growth rates into the next century. The assumed constant death rate of 15 would require a world life expectancy of 67 yr over the forecast period. The likely rate of change in life expectancy (80 yr seems optimistic) does not affect my

conclusions. The model is less optimistic than either ref. 4 or the UN 1968 "medium" forecast.

The food model has been based on similar mathematical transition curves as Fig. 2*c* and equation (1), but starting at a low initial asymptote and reaching an upper limit, specified near the best fed European dietary levels in grain equivalent calories; this is almost twice the present world average. For the present, distribution questions within each modelled area are neglected. Increase in food per capita is assumed to arise mainly from intensified agriculture, but in China and India some increase in arable land has been assumed.

I am now in a position to discuss briefly the computer runs partly shown in Fig. 3*a–f*. I assume that if trade becomes more significant (the reverse seems true at present), it will be to the

general benefit if it persists. The pattern of change in population growth was assumed to follow equation (1) with $\tau_c = 10$ yr. This assumes a "transition" to proceed from 90% ($B_0 - 15$) to 10% ($B_0 - 15$) in some 3 generations, between the Japanese and the estimated Taiwan prototypes. The inflection point was estimated crudely from such data as could be gleaned^{4,15} on vital rates for the past 10 to 20 yr¹⁵. Food increases were then adjusted to two constraints: that their slope should match, in per capita terms, the slopes in ref. 11 (p. 4), and that τ_c for food increase should be 15 yr (slower than population change transition) if a feasible fit could be found by simulating changes in τ_0 . This did not prove workable in the case of India, but the demonstrated success of the "green revolution" in terms of yield per acre seemed to justify a use of $\tau_c = 10$ yr for that subcontinent.

Both in terms of future growth prospects and food limitations, India–South Asia is the world's most worrisome area. The first food "peak" is the result of modelling the "green revolution", but not its labour disposal problems. I believe that the amount shown is feasible, but that it would not be chosen. Unemployment or distribution problems are signalled by this feature in the model.

The intent of these very simple models is neither to forecast, even implicitly, the levels reached in either population or food, or to forecast "normatively", to set a target and then to deduce what is needed to achieve it. The question here is much more restricted: given assumptions about population, is it necessary to assume agricultural expansion rates and levels, as well as learning rates that are clearly unachievable? If, on the contrary, such improvements have been obtained in the past, then it is assumed feasible to do so again elsewhere. The pattern of population growth may be capable of greater control than here assumed—then greater latitude exists to deal with food more deliberately and with lower stress on world ecology. My pattern of simulation is only concerned with disclosing "feasible regions" (see refs 6 and 19).

In refs 1 and 2, natural resources played key roles. I assumed above that for gross effects, perceiving and learning early could help us avoid disaster from these major variables. In

Fig. 3 Feasible food supplies, for modelled populations, in five regions. *a*, North America; *b*, "extended" Europe (including USSR, Japan, Australia and so on); *c*, South America and Africa; *d*, "extended" China (including UN "East Asia"); *e*, "extended" India (including UN "South Asia") and shaded "spurious" area; *f*, summation of *a* to *e* with shaded "spurious" area. This simple addition neglects international trade, at the moment negligible between these groups (except perhaps Europe, the United States and so on, and South America and the developed countries) compared with the uncertainty of data and even more of projections. 1, Arable land (10^6 hectares); 2, population (10^6); 3, food per capita (kg/yr grain equivalent); 4, modelled birth rate per thousand; 5, intrinsic modelled death rate per thousand; 6, population (10^6); 7, industrial output per capita (nominal scaling, \$/yr).

making this assumption, I do not have to presume an exponential or even faster growth of knowledge: for many of these issues, knowledge exists, and as only finite increments of population need be served, the needed increment in knowledge is modest. Its expense may, in fact, lower the future demand in the third world for particular goods now thought desirable in developed countries. Again quite crudely, and assuming multiplier functions opposite in sign to equation (1) for learning but like equation (1) for saturating demand for natural resource intensive industry^{7,8}, I have run the model for each sub-continent and found the increases in "demand" to be "staggered" over several decades (summarised in Fig. 3f). On a similar basis, I have made parameter and policy changes in the model of ref. 2 and have obtained stable and feasible (though different) values (Fig. 4).

Again, no forecasts are implied, but the question is posed: is it inconceivable for us to learn in time? The answer, that it is conceivable, means that more detailed investigations including local preferences and policy choices have a feasible possibility region to explore in medium range studies. These may be urgent: as each decade passes, the progress of events modifies what remains feasible. The principal question is: How may the most rapid solutions be found?

One of the less obvious results of the decrease in death rate (Fig. 2) and its discussion is the disproportionate increase in the average working life span. With life expectancy of 40 yr the working life is 25 yr; but a 24 yr life expectation corresponds to a working life of only 9 yr. Thus in recent years, the pos-

become an increasing problem. The number of people is a conservative measure. Thus they provide a better measure of events than money in early stages of development, where exchange has not reached major population groups, or in comparisons across great differences of development¹⁶.

The extensions proposed to the sub-models presently

Implications of anticipated extensions based on prior work are: (a) As dependency ratios drop, food output per person can increase (as it appears to have done in the past 5 to 15 yr). Further increases can readily come from accumulation of

I thank Mr R. Ritchie for discussions, Mr G. Berry for computational assistance, Professor D. L. Meadows for details of one of his models, the referees for suggestions, and the Waterloo Faculty Research Fund for financial support.

Nobel Prizes for Oxford Authors

Oxford University Press warmly congratulate Nikolas Tinbergen and Karl von Frisch on being jointly awarded, with Konrad Lorenz, the 1973 Nobel Prize for Medicine. In their work – Professor Tinbergen's on birds, and Professor von Frisch's on bees – they had, said the citation, revitalized the study of animal behaviour.

The books by Professor Tinbergen in Oxford's list are *The Study of Instinct* (£2.75), 'indispensable to all serious students of animal behaviour', according to *Nature*; *Tracks*, illustrated by E. A. R. Ennion (£2); and *Signals for Survival* (£2). The last-named, written jointly with Hugh Falkus and with illustrations by E. A. R. Ennion, describes the sign-language of the Lesser Blackbacked Gull.

In *The Dance Language and Orientation of Bees* (£6.50), Karl von Frisch describes the fascinating discoveries made during fifty years of study. 'The book is an object lesson in patient and skilful observation coupled to ingenious experimental technique.' – *The Entomologist's Record*. It is published by Oxford for Harvard University Press.

BOOK REVIEWS

Science and Capitalism

Autocritique de la Science. Edited by Alain Jaubert and Jean-Marc Levy-Leblond. (Collection Science Ouverte.) Pp. 383. (Editions du Seuil: Paris, 1973.) n.p.

It is no longer particularly original or bold to cry out against science and its misapplications. This collection of characteristic texts, mostly of French origin but many translated from English and several from Italian, is significant mainly because it attempts a comprehensive attack from the standpoint of revolutionary socialism. The material is drawn from articles, speeches and pamphlets written by scientists for other scientists on topics ranging from military research to the underemployment of women. With styles ranging from the purest Cartesian analysis to a call for strike action against the *patron* of a *labo*, it is difficult to achieve a unified approach, but the editors have chosen shrewdly and have set each piece in context with a brief introduction. The book can, therefore, be read not only for the individual texts but as a reasonably well balanced exposition of the point of view of a small but not insignificant fraction of the scientific community in France and many other Western nations.

The ideological framework is explicitly Marxist. But there is little evidence of a deep and thoroughgoing analysis of the role of science in contemporary society. An attempt to revise the theory of surplus value to cover scientific work runs away into the sands, and Roqueplo's incisive "eight theses" succeed admirably in not distinguishing between capitalist and socialist science. For most of these authors (including the editors) it seems that a primitive conception of the class struggle and a gut reaction in favour of the correct side in various wars (especially Vietnam) are sufficient ideological justification for political comment and action.

This simplification of the historical and sociological background is a grave defect in the discussion of the militarisation of research. It is easy to renounce financial support from defence organisations and to denounce academic scientists who put themselves at the service of the soldiers in a manifestly unjust war. But the roots of gangsterism, tribalism, patriotism, and nationalism are not nourished exclusively by capitalism: and a brief reference to "state capitalism" does not deal adequately with science in the Soviet Union, for example, which is equally regimented

Other noxious applications of science and technology are also interpreted as obvious consequences of the devotion of the capitalist ruling class to the maintenance of their power and profits. But several forceful theoretical papers at the beginning of the book make much of the practical incompetence of technocracy and of scientism. In their political and economic analysis the authors attribute too many of our present follies to clever conspiracies by the power élite, and do not allow sufficiently for the misplaced but universal popular belief that social problems can be solved by specialist skills and technical expertise. This applies particularly to the state of science in the Third World, where much more positive thinking is needed about how to bring genuine scientific benefits to the people. Bad education in and about science can certainly be blamed, but cannot itself be entirely explained away as a reflection of class domination.

Coming nearer home, the discussion of the actual position of the scientific worker is much more realistic. Whether or not this exemplifies the Marxian prediction of the general proletarianisation of the professional classes ("lackeys of the bourgeoisie"?), the increasing exploitation and repression of the individual scientist in the era of bureaucratic big science is a very significant phenomenon, whose psychological and political consequences are vividly depicted in these pages. Some of the current problems emphasised here, such as the gross abuse of power by research bosses, are exacerbated in France by the peculiar organisational structure of universities and scientific institutes, but we must not be complacent about such serious issues as graduate unemployment, the equivocal position of graduate students, uncertainty of tenure amongst research workers, the subordination of skilled technicians, etc. Here again, the plea for solidarity in the face of the class enemy does not resolve all questions. The relationships between an élite of *mandarins* and the body of younger *scientifiques* from whom they have been selected by harsh competition are not exactly equivalent to those between capitalist and worker, and belong more to anthropology than to political economy.

Perhaps I have said enough to show that "self-criticism" of science is an essential activity, by which many matters of the most serious concern can be brought to light. But to point a finger of bitter censure at a scandal, a crime, or an injustice, is only the first step. An

as well as of science—demands an eye for relevant evidence, an open mind towards many theoretical possibilities, and perhaps a little more of the intellectual modesty and scepticism that scientists are themselves supposed to acquire through practising their profession.

JOHN ZIMAN

Irradiating Bone

The Effects of Irradiation on the Skeleton. By Janet M. Vaughan. Pp. xvi+297. (Clarendon: Oxford; Oxford University: London, March 1973.) £7.75.

THERE is now a large body of information on the important and, at times, emotive subject of the effects of irradiation on bone. This has appeared for the most part in the regular journals but considerable numbers of researches have been published in books reporting the proceedings of specialist conferences. In her book, Dame Janet Vaughan, herself a researcher of great distinction in this field, has brought together these scattered and largely uncoordinated researches into a well informed and balanced synthesis. The book is written from the biologist's viewpoint but has the merit that the biological findings and the physical properties of radiation are related in an unusually perceptive way. The result makes rewarding reading for those in both the biological and physical sciences.

At the beginning of the book the nature of radiobiological action and the characteristics of ionising radiations are dealt with briefly, with consideration of the structure and physiology of the skeleton that are relevant to the irradiation of bone. There follow two chapters discussing in detail the tissues of bone that are at risk, the types of radiation induced cancer that can arise, and the sites of the tissues of tumour origin. A chapter is devoted to the effects of external irradiation, analysing the evidence, for example, of leukaemia induction in human populations, and the problems of internal irradiation are then considered generally in chapter 6.

A most important part of the book deals individually, in separate chapters, with the well known bone-seeking radionuclides: radium, with the dramatic series of radium poisoning cases that occurred mainly in the earlier decades of this century; the strontium isotopes; the isotopes of plutonium, americium and thorium that are deposited on bone surfaces; lastly radiophosphorus and other less known and less used radionuclides. One of the most useful

of some 700 papers, quoted with full titles, together with the page numbers in the text to which they refer. This is far more useful to a reader than an author index.

The book is written with great lucidity and is well produced with only very few and very minor misprints apparent. The synthesis achieved in this book will be a most valuable asset to those actively working on bone, but it should have a wider appeal in other fields, for example in nuclear medicine, radiotherapy, cancer research and radiation protection. This work will remain an authoritative and enlightening guide to the long term researches that are going on in many laboratories on the effects of skeletal irradiation.

F. W. SPIERS

Animal Sociology

Organisation in Animal Communities: Experimental and Naturalistic Studies of the Social Behaviour of Animals. By Hilary O. Box. Pp. 251. (Butterworth: London, March 1973.) £5 cloth; £2.50 paper.

THIS book, which grew out of a course of lectures given to psychology students at the University of Reading, touches upon a wide range of behavioural phenomena which can loosely be described as social in the sense that in some way they concern interactions between animals. There are descriptions of the social life of many animals and the book is a quite useful, although cursory, account of some of the work which has been done on social behaviour. "Social" is taken very broadly, and mimicry and parasitism are among the subjects undertaken. In addition there are sections on the influence of early experience, particularly deprivation of various sorts, on subsequent social responses, a chapter on communication and a brief survey of the social behaviour of some domesticated animals. The effects of overcrowding and the role of behaviour in the determination of animal numbers are also discussed.

Detailed and comprehensive coverage of all these topics is clearly impossible in only 251 pages, but even with this space limitation, one would have thought that there should have been room to discuss certain important questions which are in fact omitted or not faced squarely. For example, it is surprising that in a chapter which compares insect and human societies, there should be no mention of the fact that the apparent "altruism" shown by many of the social insects is probably related to the uniquely close genetic relationship between individuals in a colony¹. To say that "We now accept that social

petition and mutual aid" (page 6) without discussing such variables as the degree of genetic relationship within a social group simply sidesteps important questions of how natural selection works.

In short, this book has been written by a psychologist, and it shows.

MARIAN DAWKINS

¹ Hamilton, W. D., *Am. Nat.*, 97, 354 (1963).

Limited Omnivorousness

Seed to Civilization: The Story of Man's Food. (A Series of Books in Biology.) By C. B. Heiser jun. Pp. xii+243. (W. H. Freeman: San Francisco and Reading, July 1973.) £3.60 cloth; £1.50 paper.

MAN can appropriately be described as omnivorous. Nevertheless, like other animals, his selection of food is influenced by the complex web of compulsions by which his behaviour is moulded. That is to say, he is subject to the natural history of the species. This is as true today as it ever was. As Professor Heiser points out at the beginning of his book, there is no reason to assume that we are any more intelligent now than were the people who invented agriculture ten thousand years ago. It is, therefore, not surprising that even after having described, for the benefit of the general reader for whom this popular exposition is intended, a varied selection of fact and opinion he reaches the conclusion that "the explanations of why and how man 'invented' agriculture . . . are far from certain".

The valuable substance of the book is contained in the chapters in which the origin as human food of the species of animals and plants selected for domestication is described. There is an interesting narrative of what is known of the dog's becoming in 8400 BC man's dumb friend, with a charming illustration of a clay figure from Mexico of a dog specially fattened on maize for the table. The history of the sheep as mutton goes back eleven millenia and the goat about as far. Cattle came later although aurochs, it seems, were worshipped for a long time before they were eaten. The stories of the more exotic animals, the turkey and the Muscovy duck from the Americas, the guinea pig, and the llama from Peru, are narrated as well. It is not surprising that Heiser, a botanist, devotes forty-eight pages to an excellent chapter about grasses, ranging from wheat to bamboo. This chapter, like the rest of the book, is well illustrated with drawings and photographs from many parts of the world and many periods of history. Other chapters deal with legumes, roots,

the Cruciferae, comprising a dozen forms from cabbages to rutabaga, with gourds, nuts, coffee and pepper.

All this is informative, interesting, wide-ranging and well suited for the students of general biology, economic botany, anthropology and home economics at whom, according to the publishers, the book is aimed. A three-page chapter about nutrition is less satisfactory and seems a whit perfunctory. That the only table in it should be of the amino acid contents of various proteins owes more to today's fashion than to the major priorities of physiological need. But it is in his last chapter that we leave behind such delights as the account of the breadfruit, *Artocarpus altilis*, and the troubles that Captain Bligh encountered in transporting 1,000 young breadfruit trees from Tahiti to the West Indies (he succeeded in the end). Instead, there come the all-too-familiar ill-thought-out adumbrations about the population explosion and the "corrupt, inefficient and unstable governments" from which hungry nations suffer. There are quotations from strings of those pessimistic books, mostly written by chemists and biologists, about what "government" should do to succour developing nations. Not everyone agreed with all the rude things that Professor Wilfred Beckerman had to say about the blunders of chemists and biologists when they ignore the existence of political economy as a well established discipline in its own right; but enough of them were sufficiently incontrovertible, one would have thought, to discourage otherwise well-judging authors like Professor Heiser from allowing their feelings to draw them away from the topics upon which they are worth reading to the ritual obeisance to the starving millions.

MAGNUS PYKE

Development

Developmental Biology: Its Cellular and Molecular Foundations. By Maurice Sussman. (Foundation of Modern Biology Series.) Pp. xvi+297. (Prentice-Hall: Englewood Cliffs, NJ, and Hemel Hempstead, March 1973.) £3.50 paper.

DR SUSSMAN's book is written in an engaging and buttonholing style that has the vigour (and the jokes) that will be familiar to those who have heard him lecture. This inimitable style is admirably suited to his purpose which is to demonstrate "the extraordinary power of science as a method of asking questions properly and answering them with rigour." Much of the book is written in the Socratic tradition as interpreted by modern molecular biologists and provides an excellent and compelling intro-

the fundamental aspects of developmental biology. There is a danger, of course, that the beginning student (who is admirably catered for with two introductory review chapters) may not realise that what is being presented is a particular point of view. The preface makes this quite clear but I would have liked to see, perhaps in the bibliography which is given at the end of each chapter, some reference to opposing viewpoints to counter the somewhat dogmatic tone of parts of the text. I doubt, for example, if all would agree that "the only reasonable interpretation" of Dr Mintz's experiments on allphenic mice is the one that she has suggested; and the treatment of morphogenetic fields is curiously old fashioned. These are, however, minor criticisms of a book which can be recommended to both undergraduate and postgraduate students and which will be invaluable as a source-book of provocative and pungent statements for those who organise seminars and set examination papers.

J. M. ASHWORTH

Bird Biology

Avian Biology. Edited by Donald S. Farner and James R. King. Taxonomic Editor: Kenneth C. Parkes. Vol. 2. Pp. xxiii+612. (Academic: New York and London, December 1972.) \$32.

SOME ten years ago, A. J. Marshall edited two volumes on the biology and physiology of birds. This volume is the second in a series of three which provide an updated and much needed replacement for Marshall's work. There are new editors, almost all new authors, a different organisation, and more complete coverage.

The volume at hand (volume 2) has three chapters dealing with feathers; the remaining six deal with specific physiological systems such as respiration and circulation. This selection can best be evaluated in the context of the complete series. Volume 1 (already published) has four chapters of more or less classical ornithology and seven oriented towards ecology. Volume 3 (to be published) will deal with reproduction and endocrine systems (four chapters), and with senses and behaviour (another four chapters).

Does this cover the area of avian biology? One could instead ask, what are the most characteristic aspects of bird biology? It seems that these are (1) birds are warm blooded and have feathers, (2) they fly and migrate over long distances, and (3) they have a characteristic mode of reproduction. Some of these subjects are well covered; feathers have three chapters of volume 2, and reproduction will come in volume 3. But there are no individual

or on thermoregulation. I find a lack of balance here, for endocrinology will have three chapters, and substantial sections on endocrinological control will appear in two more.

Volume 2 contains nine chapters which, as can be expected, are of uneven quality. Most presentations are good and a few are outstanding. Some could be criticised. Chapter 2, ("Patterns of Molting") is from the beginning steeped in terminology which is poorly or not at all defined, and is difficult to follow for a non-specialist. Chapter 7 ("Nutrition") is, as the author states, restricted mainly to the domestic chicken. True enough, most nutritional studies on birds are on chickens, but nevertheless I see no need for the extensive discussions of animal husbandry and the many tables on the nutritional value of commercial feed ingredients. A stronger editorial hand would have been helpful for this chapter, and for the following one ("Intermediary Metabolism"), which seems to be well organised and contains much information but suffers from lack of perspective. With these items to criticise, we are left with a volume that contains mostly good and excellent papers.

There are separate indices for author names, for bird names and for subjects. The publisher deserves praise for making these very helpful tools available to the worker who uses the volumes for constant reference.

KNUT SCHMIDT-NIELSEN

Elementary Particles

Particle Physics: An Introduction. By M. Leon. Pp. xii+268. (Academic: New York and London, March 1973.) \$14.50.

PARTICLE physics is a very difficult subject to teach at introductory level. It has a vast glossary of jargon and there is a large set of intriguing and profound data. But the theoretical framework, which will one day unify the subject, is still lying about as a kit of parts. The kit may be almost complete, but no one has been able to put it together.

This book treats the main theoretical components in an admirably concise way. There are reasonably thorough treatments of scattering theory and quantum-field theory, with brief discussions of quantum electrodynamics, hadron dynamics and weak interactions. Particle properties are presented, with emphasis on symmetries, including SU(3). Such recent developments as dual models, or unified weak and electromagnetic theories, are quite rightly omitted.

Although the preface claims that this text is useful for "seniors and graduate students", the material is too advanced

probably inevitable in a book which covers so much of the theoretical kit. A sensible starting point for undergraduates is the much more experimental book of I. S. Hughes (Penguin library of physical sciences). For first-year postgraduates, however, this book promises to be extremely useful.

DAVID J. MILLER

Neonatal Anatomy

Functional Anatomy of the Newborn. By Edmund S. Crelin. Pp. xii+87. (Yale University: New Haven and London, February 1973.) £3.50 cloth; £1.75 paper.

THIS somewhat dry and colourless book is an attempt by an anatomist to provide "a concise guide to be used by all personnel involved in one form or another with the newborn infant, including students". The author is a consultant to the Newborn Special Care Unit at Yale and assists in the evaluation of newborn infants with birth defects.

This book has a mere seventy-one pages of text and only three illustrations. These are line drawings by the author, one illustrating all the ossified parts of the skeleton in the full term newborn infant, the second a sort of see-through, half frontal, topographic anatomy of the full-term newborn infant, and the third a mid-sagittal section.

There is no subdivision into chapters or sections, but sequential descriptions of various tissues or organs. The order is based on that of the larger atlas produced by the author a few years ago.

There are some potentially useful statistics in the text, but it is difficult to see of what practical value much of the information can be to the practising paediatrician, pathologist or obstetrician. Thus, the opening section on body weight, size and proportions states that "the average full-term infant (8½ months) weighs about 3,300 gm (7 lb) and the average crown-heel length is about 50 cm (20 inches)", whereas "a premature newborn infant (7 months) weighing only 1,200 gm (3 lb) would have a crown-heel length of about 38 cm (16 inches)". No information is given for any other gestational age. How much more useful would have been a table or graph showing the increase in weight and length with gestation.

Throughout the book there is very little reference to the functional anatomy at various stages of gestation.

Occasional sections do have a few useful details, with some of the implied clinical applications. Thus the development of the lung and its structure is done in some detail and includes comment on surfactant; and the cardio-

detail. In contrast the epidermal ridge pattern of the fingers and palms is dismissed in a single comment that they are unique to the individual, and the section on the brain has practically no comment on its changes during foetal development.

This book is difficult to read as a continuous text, and as a source of reference I think people will prefer the more comprehensive neonatal clinical texts available on various systems.

VICTOR DUBOWITZ

Nutritional Technology

Introduction to Food Science and Technology. By George F. Stewart and Maynard A. Amerine. Pp. xiii+294. (Academic: New York and London, January 1973.) \$12.50.

Food science differs from other sciences in drawing on a wider range of disciplines for its techniques; the authors have done well to cover most of them in less than 300 pages. Each chapter is a wide ranging survey of a subject starting with an introduction to the basic concepts and generally succeeding in indicating its scope and depth. The selected references given at the end of each chapter provide a useful introduction to some more detailed sources of information.

The book centres around an excellent chapter "Food processing and preservation" which summarises the diverse techniques used and explains the scientific basis of each. Examples are taken from commercially available products to illustrate these preservation techniques and to explain some of the technological problems encountered with each.

The book starts with a brief history of the development of food processing and then summarises the world food situation, emphasising the important role that food technology will have to play in resolving the world food crisis. There is then a chapter on food quality and its assessment (surprisingly the least successful in my opinion) followed by a survey of human nutrition which includes a section on the effects of raw material handling, processing and storage on the nutritive value of food.

After the chapter on food processing and preservation there are shorter chapters on packaging, safety and sanitation (which includes water supply and effluent treatment), food laws and careers in food science and technology. These last two chapters refer mainly to the United States but still make worthwhile reading for the British student.

Almost all foods are manufactured from natural products and consequently all workers in the field (both scientists

terms with the variability of their raw material. To do this it is essential that they have some knowledge of statistics and agriculture and for this reason I regret that the authors chose not to include a chapter on either subject. Perhaps the inclusion of two further chapters would have increased the cost beyond the means of the "prospective food scientists and technologists" for whom it was written.

The authors must be congratulated on condensing so much of the essence of food science into this book and on maintaining a comprehensible and readable style throughout. It would be a useful addition to the bookshelf of any student of food science as well as to that of graduates of other disciplines starting work in the field.

JOHN WOODMAN

Ethylene in Plants

Ethylene in Plant Biology. By Frederick B. Abeles. Pp. xii+302. (Academic: New York and London, June 1973.) \$18.50.

THERE was a time when auxin was invoked as the master controller of all plant growth and developmental processes. It now seems that ethylene, whose dramatic effects on plants have been known for more than 70 years, is rapidly slipping into that role. In the past 10 years there has been a veritable explosion of research into the physiological actions of ethylene directed towards assessing its significance as a 'natural' hormone.

Dr Abeles has made a thorough survey of the bulky and confusing literature on this topic from the earliest indications of ethylene damage to plants over a century ago to the most recent and sophisticated biochemical and physiological studies. The topics covered are far ranging and include such matters as the practical use of ethylene and related compounds in plant production, the part played by ethylene as an air pollutant, its chemistry and analytical techniques for its estimation. Anybody interested in plant hormones and the chemical control of plant growth and development will find this a mine of information and references.

Having read the book from cover to cover, however, the reader will still be in doubt as to the importance and significance of ethylene as an endogenous growth regulator. Ethylene seems to do everything, but inconsistently, and all this is reported thoroughly and fairly. Although Dr Abeles is clearly a believer in ethylene as a major plant hormone, he has been unable to weave from this tangle of the literature a logical story to convince the sceptic. But he should not be criticised on this score; the time honoured auxin saga is no clearer.

Whatever happened to John Maddox?

Smoking in Pregnancy

SIR,—It seems likely that smokers, in general, lead a markedly different life-style from non-smokers, and that the life-style of the smoking mother during pregnancy may be less supportive of the developing foetus. So it is proper to be cautious in interpreting the association between maternal smoking and perinatal death.

In this context, Professor Burch (*Nature*, 245, 277; 1973) notes the evidence, and it is strong, that the low-birth-weight babies of smoking mothers are healthier than those of non-smokers. He seems to suggest that this, too, is evidence against the hypothesis that maternal smoking causes perinatal deaths. Is it not more reasonable to interpret it as merely evidence that maternal smoking is not so harmful to the infant as other causes of low birth weight? In general these causes are very powerfully associated with perinatal death: infants weighing 2,500 g and less at birth are sixteen times more likely to suffer perinatal death than those weighing more than 2,500 g (ref. 1).

Suppose that maternal cigarette smoking causes a weight loss of 5% in each baby: and suppose that each such baby has a 25% greater chance of suffering perinatal death than it would have if the mother had not smoked. Then consider that class of babies weighing less than 2,500 g and born to smoking mothers. About half of them are in that class for no reason other than that, having been born to smokers,

their weight has been reduced, thus transferring them from the heavier class to the lighter one. *Ex hypothesi*, their probability of perinatal death is 25% greater than it would have been if their mother had not smoked. But it is far less than that of the other babies in that class—those who would have been in that class whether their mothers had smoked or not.

In short, the effect of smoking is to augment that class with some relatively healthy babies. So it seems to me that the observed interaction between maternal smoking and birth weight, far from being mysterious, is exactly what would have been expected on the hypothesis that, besides depressing birth weight, maternal smoking has a rather weak causal association with perinatal death.

One would expect a similar interaction between birth weight and any factor if that factor both depressed birth weight and slightly increased the probability of perinatal death.

Let us consider social class, twinning and race. Babies of low social class have higher perinatal mortality rates and lower birth weights than babies in the upper social classes. For weights greater than 3,000 g there is a steady increase in perinatal mortality as social class declines. In the weight class 2,501 to 3,000 g, however, there is a steady decline in mortality rate as social class declines. And in the weight classes less than 2,500 g, there is further evidence that babies born to upper-class mothers are not the healthiest².

Twins have higher perinatal mortality

rates and lower mean birth weights than singletons. However, low-birth-weight twins have a better chance of survival than low-birth-weight singletons³⁻⁶.

In the United States non-white babies have lower mean birth weights and a higher perinatal mortality rate than whites. Nevertheless, among low-birth-weight babies, the non-whites have lower neonatal mortality rates than the whites⁷. In regard to stillbirth rates there is also an interaction (Table 1).

Each of these interactions, viewed in isolation, may be perplexing at first sight. But when seen in conjunction with others, there seems a common-sense explanation behind all of them. I suggest that it applies to maternal cigarette smoking too.

Yours faithfully,

WILLIAM H. JAMES

Obituary

Professor E. A. Stewardson

PROFESSOR E. A. STEWARDSON, Emeritus Professor of Physics, Leicester University, who died on August 24, 1973, at the age of 68, was born in 1904, and educated at Hawarden County School, North Wales. He graduated from the University of Liverpool in 1924 with first class honours in physics

and took his MSc in 1925. After holding appointments at the University of Liverpool and the National Central University, Chungking, he came to Leicester University College in 1940 and became the first Professor of Physics in 1946. He retired in 1969.

Professor Stewardson's main interest was what nowadays would be called 'atomic physics' rather than 'modern

physics' and a great deal of his research was spent on soft X-ray spectroscopy. Over the years he developed considerable experimental expertise in this field and this was to prove a valuable asset in the latter part of his scientific career.

Professor Stewardson was also a keen amateur astronomer and when, in the late 1950s, it was decided that part of the UK space research programme

should be to investigate the soft X-ray emission of the Sun, it was no surprise that Professor Stewardson's ability was called upon. A collaborative venture between the Universities of Leicester and London ensued, and in 1961 the first direct spectral data for solar soft X-rays were obtained by mounting a soft X-ray spectrometer on a rocket. During the next few years a group devoted to the soft X-ray side of space physics was set up under the direction of Professor Stewardson at the University of Leicester. Some of the successful joint experiments were those on an orbiting solar observatory in 1967 and 1968 and the recently acclaimed X-ray telescope array.

In parallel with the space application of soft X-ray spectroscopy, Professor Stewardson maintained a strong interest in other aspects of atomic physics. He was interested in electron-nuclear collisions and supervised the building and operation of a van de Graaff accelerator in Leicester in the early 1950s.

He will be missed by his colleagues and friends at Leicester.

Announcements

Appointments

THE following have been appointed members and officers of the **International Office of Radiological Protection** for 1973-77. Chairman, **Dr C. G. Stewart** (Canada), **Professor B. Lindell** (Sweden), **Dr D. J. Beninson** (Argentina), **Dr H. Jammet** (France), **Dr J. Liniecki** (Poland), **Dr A. S. McLean** (Great Britain), **Professor Y. I. Moskalev** (USSR), **Dr H. B. Newcombe** (Canada), **Dr E. E. Pochin** (Great Britain), **Professor S.**

Takahashi (Japan), **Professor A. C. Upton** (USA), **Dr J. Vennart** (Great Britain), **Professor Sir Brian Windeyer** (Great Britain). Members Emeritus, **Professor K. Z. Morgan** (USA) and **Dr L. S. Taylor** (USA). Scientific Secretary, **Dr F. D. Sowerby** (Canada).

Professor Francis O'Grady, University of London, has been appointed to the Foundation Chair of Microbiology, University of Nottingham.

The following have been appointed members of the Natural Environment Research Council: **Professor F. G. T. Holliday**, **Professor A. W. Skempton**, **Dr R. G. West**, **Dr I. Maddock**, and **Mr D. J. Lyons**.

Dr K. Hellmann of the Cancer Chemotherapy Unit, Imperial Cancer Research Fund, has been appointed Visiting Professor of Cancer Chemotherapy to the Westminster Medical School, University of London.

Errata

IN the bibliography of the book *Notes on the History of Nutrition Research* (reviewed *Nature*, 245, 442; 1973) the publisher and prices should have read: (Huber: Stuttgart, Berne and Vienna, 1973.) 42 Sw. fr.; 38 DM.

IN the article "Model for the Mating Protocol of Synchronously Flashing Fireflies" by J. E. Lloyd (*Nature*, 245, 268; 1973) paragraph 11, line 7 and following, should read "This is not apparent and perhaps does not occur in most *Pteroptyx* species. I spent many hours within swarms watching individuals and once saw this: a male received a luminescent response to his signals from a female 30 cm away and walked to her and mounted her immediately".

International Meetings

December 3, **The Bragg Lecture** (Dr H. Judith Milledge, Secretary, Bragg Lecture Fund Committee, Chemistry Department, University College London, Gower Street, London WC1).

December 17-21, **Marine Waste Disposal and Marine Pollution** (Istituto di Ingegneria Sanitaria del Politecnico di Milano, Segreteria per i Convegni Internazionali, Piazza Leonardo da Vinci 32, 20133 Milan).

December 18, **Second Scottish Perkin Symposium** (Professor P. L. Parson, Department of Pure and Applied Chemistry, University of Strathclyde, Cathedral Street, Glasgow G1 1XL).

December 18-19, **545th Biochemical Society Meeting** (Meetings Officer, The Biochemical Society, 7, Warwick Court, Holborn, London WC1R 5DP).
